# A PROBLEM OF ERDÖS-SZÜSZ-TURÁN ON DIOPHANTINE APPROXIMATION 

MAOSHENG XIONG AND ALEXANDRU ZAHARESCU

## 1. Introduction

In an old paper [7] on diophantine approximation, Erdös, Szüsz and Turán considered the set of real numbers $S(m, \alpha, c)$ defined by

$$
\begin{array}{r}
S(m, \alpha, c)=\{\xi: \quad 0 \leq \xi \leq 1, \text { there exist integers } a, q \text { for which } \\
m \leq q \leq m c, \operatorname{gcd}(a, q)=1,|q \xi-a| \leq \alpha / q\},
\end{array}
$$

where $m \in \mathbb{N}, \alpha>0, c \geq 1$. They studied the Lebesque measure $\mu(S(m, \alpha, c))$ of $S(m, \alpha, c)$, and showed that

$$
\begin{equation*}
\lim _{m \rightarrow \infty} \mu(S(m, \alpha, c))=\frac{12 \alpha}{\pi^{2}} \log c, \tag{1}
\end{equation*}
$$

provided $\alpha \leq c /\left(1+c^{2}\right)$. Then they raised the following problem:
Problem. For $\alpha>0, c \geq 1$, does the limit

$$
\begin{equation*}
\lim _{m \rightarrow \infty} \mu(S(m, \alpha, c)) \tag{2}
\end{equation*}
$$

exists, and if so, what is its explicit form? (see also [6]).
The topic was later developed by Kesten [20], who, building on previous work of Friedman and Niven [17], proved that the limit (2) exists in the wider range $\alpha c \leq 1$ and obtained the following formulas for the limit:

If $c \geq 1$ and $c /\left(1+c^{2}\right) \leq \alpha \leq \min (1 / 2,1 / c)$, then

$$
\begin{align*}
\lim _{m \rightarrow \infty} \mu(S(m, \alpha, c))= & \frac{12 \alpha}{\pi^{2}} \log c-\frac{12}{\pi^{2}}\left(\alpha c+\frac{\alpha}{c}-\alpha \beta-\frac{\alpha}{\beta}\right. \\
& \left.+\alpha\left(\frac{1}{\beta}-\beta\right) \log \frac{c}{\beta}-\frac{1}{2}\left(\log \frac{c}{\beta}\right)^{2}\right), \tag{3}
\end{align*}
$$

where

$$
\beta=\frac{1+\left(1-4 \alpha^{2}\right)^{1 / 2}}{2 \alpha} .
$$

If $1 / 2 \leq \alpha \leq 1 / c$, then

$$
\begin{equation*}
\lim _{m \rightarrow \infty} \mu(S(m, \alpha, c))=\frac{12 \alpha}{\pi^{2}} \log c-\frac{12}{\pi^{2}}\left(\alpha c-2 \alpha+\frac{\alpha}{c}-\frac{1}{2}(\log c)^{2}\right) . \tag{4}
\end{equation*}
$$

Finally the problem was solved by Kesten and Sós ([19]), who, based on a result concerning another problem posed by Erdös, Szüsz and Turán in the same paper ([7]), proved that the limit (2) exists for any $\alpha>0, c \geq 1$ without actually finding explicit formulas in the general case. Our approach below relies on the development in recent years of the theory of local spacing distribution of visible lattice points and related objects, which equips one with enough tools to attack this problem directly. The first goal for us is to give another proof of the existence of the limit (2) for all $\alpha>0, c \geq 1$, and along the way obtain explicit formulas to compute it. This is Theorem 2 in Section 4.

Second, once the limit (2) is established, call it $\rho(\alpha, c)$, a natural question that arises is the following: How is this positive mass of measure $\rho(\alpha, c)$ distributed inside the interval $[0,1]$ ? Is it uniformly distributed? In other words, for any subinterval $\mathbf{I} \subset[0,1]$, if we let

$$
\begin{aligned}
& S_{\mathbf{I}}(m, \alpha, c)=\{\xi: \quad \xi \in \mathbf{I}, \text { there exist integers } a, q \text { for which } \\
& m \leq q \leq m c, \operatorname{gcd}(a, q)=1,|q \xi-a| \leq \alpha / q\}
\end{aligned}
$$

is it true that the limit $\lim _{m \rightarrow \infty} \mu\left(S_{\mathbf{I}}(m, \alpha, c)\right)$ exists and equals $|\mathbf{I}| \rho(\alpha, c)$ ? We will prove that this is the case.

Theorem 1. For any $\alpha>0, c \geq 1$ and any subinterval $\mathbf{I} \subset[0,1]$, the limit $\lim _{m \rightarrow \infty} \mu\left(S_{\mathbf{I}}(m, \alpha, c)\right)$ exists and

$$
\lim _{m \rightarrow \infty} \mu\left(S_{\mathbf{I}}(m, \alpha, c)\right)=|\mathbf{I}| \rho(\alpha, c) .
$$

As it is the case for other distribution problems where Farey fractions play a central role, such as the problem raised by Hall and investigated in [2], if one wants to understand the distribution in subintervals $\mathbf{I}$ of $[0,1]$, the key is to establish a connection between the given problem and the distribution of visible lattice points with congruence constraints. This in turn allows one to relate the problem with the distribution of inverses in residue classes, which further enables one to bring in a decisive way the Kloosterman machinery into play and ultimately solve the problem.

## 2. Farey fractions, Visible points and Kloosterman sums

We start by recalling some results on Farey fractions. For an exposition of their basic properties, the reader is referred to [10]. Let $\mathscr{F}_{Q}=$ $\left\{\gamma_{1}, \ldots, \gamma_{N(Q)}\right\}$ denote the Farey sequence of order $Q$ with $1 / Q=\gamma_{1}<$ $\gamma_{2}<\cdots<\gamma_{N(Q)}=1$. It is well-known that

$$
N(Q)=\sum^{Q} \phi(j)=\frac{3 Q^{2}}{\pi^{2}}+O(Q \log Q)
$$

Write $\gamma_{i}=a_{i} / q_{i}$ in reduced form, i.e., $a_{i}, q_{i} \in \mathbb{Z}, 1 \leq a_{i} \leq q_{i} \leq Q, \operatorname{gcd}\left(a_{i}, q_{i}\right)=$ 1. For any two consecutive Farey fractions $a_{i} / q_{i}<a_{i+1} / q_{i+1}$, one has $a_{i+1} q_{i}-a_{i} q_{i+1}=1$ and $q_{i}+q_{i+1}>Q$. Conversely, if $q$ and $q^{\prime}$ are two coprime integers in $\{1, \ldots, Q\}$ with $q+q^{\prime}>Q$, then there are unique $a \in\{1, \ldots, q\}$ and $a^{\prime} \in\left\{1, \ldots, q^{\prime}\right\}$ for which $a^{\prime} q-a q^{\prime}=1$, and $a / q<a^{\prime} / q^{\prime}$ are consecutive Farey fractions of order $Q$. Therefore, the pairs of coprime integers $\left(q, q^{\prime}\right)$ with $q+q^{\prime}>Q$ are in one-to-one correspondence with the pairs of consecutive Farey fractions of order $Q$. Moreover, the denominator $q_{i+2}$ of $\gamma_{i+2}$ can be expressed (cf. [14]) by means of the denominators of $\gamma_{i}$ and $\gamma_{i+1}$ as

$$
q_{i+2}=\left[\frac{Q+q_{i}}{q_{i+1}}\right] q_{i+1}-q_{i}
$$

where [.] denotes the integer part function. By induction, for any $j \geq 2$, the denominator $q_{i+j}$ of $\gamma_{i+j}$ can be expressed in terms of the denominators of $\gamma_{i}, \gamma_{i+1}$. More precisely, let $\mathscr{T}$ denote the Farey triangle

$$
\mathscr{T}=\left\{(x, y) \in[0,1]^{2}: x+y>1\right\}
$$

and consider, for each $(x, y) \in \mathscr{T}$, the sequence $\left(L_{i}(x, y)\right)_{i \geq 0}$ defined by $L_{0}(x, y)=x, L_{1}(x, y)=y$ and recursively, for $i \geq 2$,

$$
L_{i}(x, y)=\left[\frac{1+L_{i-2}(x, y)}{L_{i-1}(x, y)}\right] L_{i-1}(x, y)-L_{i-2}(x, y)
$$

Then for all $i, j \geq 0$ with $i+j \leq N(Q)$, we have

$$
\frac{q_{i+j}}{Q}=L_{j}\left(\frac{q_{i}}{Q}, \frac{q_{i+1}}{Q}\right)
$$

Such formulas prove to be useful in the study of various questions on the distribution of Farey fractions (see, for example [1]-[5], [11]-[14], [16], [18]). The bijective, piecewise smooth and area preserving map $T: \mathscr{T} \longrightarrow \mathscr{T}$ defined by ([2])

$$
T(x, y)=\left(y,\left[\frac{1+x}{y}\right] y-x\right)
$$

also plays an important role in recent developments of the subject. The set $\mathscr{T}$ decomposes as a disjoint union of convex polygons

$$
\mathscr{T}_{k}=\left\{(x, y) \in \mathscr{T}:\left[\frac{1+x}{y}\right]=k\right\}, \quad k \in \mathbb{N},
$$

and

$$
T(x, y)=(y, k y-x), \quad(x, y) \in \mathscr{T}_{k}
$$

For any integer $i \geq 0$,

$$
T\left(\frac{q_{i}}{Q}, \frac{q_{i+1}}{Q}\right)=\left(\frac{q_{i+1}}{Q}, \frac{q_{i+2}}{Q}\right)
$$

and

We need some more notation. Denote

$$
\mathbb{Z}_{p r}^{2}=\left\{(a, b) \in \mathbb{Z}^{2}: \operatorname{gcd}(a, b)=1\right\} .
$$

For each region $\Omega$ in $\mathbb{R}^{2}$ and each $C^{1}$ function $f: \Omega \longrightarrow \mathbb{C}$, we denote

$$
\|f\|_{\infty, \Omega}=\sup _{(x, y) \in \Omega}|f(x, y)|,
$$

and

$$
\|D f\|_{\infty, \Omega}=\sup _{(x, y) \in \Omega}\left(\left|\frac{\partial f}{\partial x}(x, y)\right|+\left|\frac{\partial f}{\partial y}(x, y)\right|\right)
$$

We need the following variations of results from [2].
Lemma 1. Let $\Omega \subset[1, R] \times[1, R]$ be a convex region and let $f$ be a $C^{1}$ function on $\Omega$. Then

$$
\sum_{(a, b) \in \Omega \cap \mathbb{Z}_{p r}^{2}} f(a, b)=\frac{6}{\pi^{2}} \iint_{\Omega} f(x, y) \mathrm{d} x \mathrm{~d} y+\mathcal{E}_{R, \Omega, f}
$$

where

$$
\mathcal{E}_{R, \Omega, f} \ll\|f\|_{\infty, \Omega} R \log R+\|D f\|_{\infty, \Omega} \operatorname{Area}(\Omega) \log R .
$$

This is Corollary 1 in [2].
For any subinterval $\mathbf{J}=\left[t_{1}, t_{2}\right]$ of $[0,1]$, denote $\mathbf{J}_{a}=\left[\left(1-t_{2}\right) a,\left(1-t_{1}\right) a\right]$.
Lemma 2. Let $\Omega \subset[1, R] \times[1, R]$ be a convex region and let $f$ be a $C^{1}$ function on $\Omega$. For any subinterval $\mathbf{J} \subset[0,1]$ one has

$$
\sum_{\substack{(a, b) \in \Omega \cap \mathbb{Z}_{p r}^{2}, \bar{b} \in \mathbf{J}_{a}}} f(a, b)=\frac{6|\mathbf{J}|}{\pi^{2}} \iint_{\Omega} f(x, y) \mathrm{d} x \mathrm{~d} y+\mathcal{F}_{R, \Omega, f, \mathbf{J}}
$$

where

$$
\begin{gathered}
\mathcal{F}_{R, \Omega, f, \mathbf{J}}<_{\delta} \quad m_{f}\|f\|_{\infty, \Omega} R^{3 / 2+\delta}+\|f\|_{\infty, \Omega} R \log R \\
+\|D f\|_{\infty, \Omega} \operatorname{Area}(\Omega) \log R
\end{gathered}
$$

for any $\delta>0$, where $\bar{b}$ denotes the multiplicative inverse of $b(\bmod a)$, i.e., $1 \leq \bar{b} \leq a-1, b \bar{b} \equiv 1(\bmod a), m_{f}$ is an upper bound for the number of intervals of monotonicity of each of the functions $y \mapsto f(x, y)$.

This is Lemma 8 in [2], where Weil type estimates ([21], [15], [8]) for certain

## 3. Two Lemmas

We first explain the strategy we will employ in investigating Erdös, Szüsz and Turán's problem, which may also be useful in the study of other problems.

For $\alpha>0, c \geq 1, m \in \mathbb{N}$, let $Q=[m c]$ and $\mathscr{F}_{Q}=\left\{\gamma_{1}, \ldots, \gamma_{N(Q)}\right\}$ be the Farey sequence of order $Q$ with $1 / Q=\gamma_{1}<\gamma_{2}<\cdots<\gamma_{N(Q)}=1$. Write $\gamma_{i}=a_{i} / q_{i}$ in reduced form. For every $\gamma_{i} \in \mathscr{F}_{Q}$, let

$$
J\left(\gamma_{i}\right)=\left[\frac{a_{i}}{q_{i}}-\frac{\alpha}{q_{i}^{2}}, \frac{a_{i}}{q_{i}}+\frac{\alpha}{q_{i}^{2}}\right] .
$$

We have

$$
S(m, \alpha, c)=\bigcup_{\gamma_{i} \in \mathscr{F}_{Q} ; q_{i} \geq m} J\left(\gamma_{i}\right)
$$

By restating the problem in the language of Farey fractions, one realizes the importance of the local spacing distribution of Farey fractions. In order to understand the limit (2), one needs to control the statistic behavior of long chains of consecutive Farey points. We want to emphasize that as $h$ increases it becomes more difficult to keep under control the behavior of an entire $h$-tuple of consecutive Farey fractions. From this point of view, Lemma 3 below, which establishes a bound for the length of any chain of consecutive Farey fractions that contribute to the measure of the given set $S(m, \alpha, c)$, is a simple, yet crucial ingredient in our proof.

Lemma 3. For any $\alpha>0, c \geq 1$, there exists an integer $K=K(\alpha, c) \geq 0$ such that for any integer $m>0$ and any $\gamma_{i}, \gamma_{j} \in \mathscr{F}_{Q}$ with $Q=[m c], q_{i} \geq$ $m, q_{j} \geq m$ and $J\left(\gamma_{i}\right) \cap J\left(\gamma_{j}\right) \neq \Phi$, we have $|i-j| \leq K$.

Proof. Assume $i<j$ and write $j=i+k$. The relation $J\left(\gamma_{i}\right) \cap J\left(\gamma_{i+k}\right) \neq \Phi$ implies that

$$
\frac{a_{i+k}}{q_{i+k}}-\frac{\alpha}{q_{i+k}^{2}} \leq \frac{a_{i}}{q_{i}}+\frac{\alpha}{q_{i}^{2}}
$$

and since $m c \geq Q \geq q_{i}, q_{i+k} \geq m$,

$$
\begin{aligned}
\frac{k}{Q^{2}} & \leq \frac{1}{q_{i+k} q_{i+k-1}}+\frac{1}{q_{i+k-1} q_{i+k-2}}+\ldots+\frac{1}{q_{i+1} q_{i}} \\
& =\frac{a_{i+k}}{q_{i+k}}-\frac{a_{i}}{q_{i}} \leq \frac{\alpha}{q_{i+k}^{2}}+\frac{\alpha}{q_{i}^{2}} \leq \frac{2 \alpha}{m^{2}}
\end{aligned}
$$

Therefore

$$
k \leq \frac{2 \alpha Q^{2}}{m^{2}} \leq 2 \alpha c^{2}
$$

and choosing $K=\left[2 \alpha c^{2}\right]$, the lemma is proved.
A concept that plays an important role in questions on the local distri-
introduced by Hall and Shiu [13]. In the language of visible points, the index is intrinsically related with the position of consecutive visible points in terms of their distance to the origin and the angle between the corresponding rays from the origin to these points, and in this way it naturally appears in some applications to questions originating in mathematical physics (billiards, periodic Lorentz gas).

Definition. For $1<i<N(Q)$, the index of the fraction $\gamma_{i}$ in $\mathscr{F}_{Q}$ is defined by

$$
v_{Q}\left(\gamma_{i}\right)=\left[\frac{Q+q_{i-1}}{q_{i}}\right] .
$$

We remark that the existence of an upper bound for the length of any chains does not imply any bound for the index. For a suggestive example, the reader is referred to Figure 2 from [1]. The idea of trying to understand an entire distribution by understanding each individual piece of it that corresponds to a fixed value of the index is very valuable in dealing with questions related with the local spacing distribution of Farey points, and we will also make use of it in this paper. Another aspect worth mentioning is the following: Fractions with large index, or $h$-tuples of consecutive Farey fractions for which at least one of the fractions has a large index, are hard to control. The reason for this is that it is hard to control the regions inside the so-called Farey triangle that produce such tuples, as they have small areas compared to the length of their boundary.

In our problem, a simple but key device is Lemma 4 below, which provides us with a uniform bound for the index of any of the fractions in any chain that contributes to the measure of the given set $S(m, \alpha, c)$.

Lemma 4. For any $\alpha>0, c \geq 1$, there exists an integer $T=T(\alpha, c) \geq 1$ with the following property: For any integer $m>0$ and any $\gamma_{i}, \gamma_{j} \in \mathscr{F}_{Q}$ with $Q=[m c], i<j, q_{i} \geq m, q_{j} \geq m$ and $J\left(\gamma_{i}\right) \cap J\left(\gamma_{j}\right) \neq \Phi$, we have $v_{Q}\left(\gamma_{s}\right) \leq T$ for any $s$ with $i<s \leq j$.

Proof. Write $j=i+k$. Since $J\left(\gamma_{i}\right) \cap J\left(\gamma_{i+k}\right) \neq \Phi$,

$$
\frac{a_{i+k}}{q_{i+k}}-\frac{a_{i}}{q_{i}} \leq \frac{\alpha}{q_{i+k}^{2}}+\frac{\alpha}{q_{i}^{2}} \leq \frac{2 \alpha}{m^{2}}
$$

For any $s$ such that $i<s \leq i+k$,

$$
\frac{a_{s} q_{i}-a_{i} q_{s}}{q_{s} q_{i}} \leq \frac{a_{i+k}}{q_{i+k}}-\frac{a_{i}}{q_{i}} .
$$

Here $a_{s} q_{i}-a_{i} q_{s} \geq 1$ and $q_{i} \leq Q$, hence $\frac{1}{Q q_{s}} \leq \frac{2 \alpha}{m^{2}}$, and so $q_{s} \geq \frac{m^{2}}{2 \alpha Q}$. Thus for any $i<s \leq i+k$

$$
v_{o}\left(\gamma_{s}\right)=\left[\underline{Q+q_{s-1}}\right] \leq \frac{Q+Q}{2(\Omega)} \leq 4 \alpha c^{2}
$$

We may choose $T=\left[4 \alpha c^{2}\right]$ and this completes the proof of the lemma.

## 4. The case $\mathbf{I}=[0,1]$

In this section we present a proof of the existence of the limit (2) and also provide an explicit formula for the limit. With the length of the chains as well as the sizes of the index bounded, we will proceed to connect our problem to the distribution of visible points inside expanding regions, which can then be treated with the aid of Lemma 1 and 2.

Using the inclusion-exclusion principle,

$$
\begin{aligned}
\mu(S(m, \alpha, c)) & =\mu\left(\bigcup_{\gamma_{i} \in \mathscr{F}_{Q} ; q_{i} \geq m} J\left(\gamma_{i}\right)\right) \\
& =\sum_{r=1}^{N(Q)}(-1)^{r-1} \sum_{\substack{1 \leq i_{1}<\cdots<i_{r} \leq N(Q), q_{i_{1}} \geq m, \ldots, q_{i} \geq m}} \mu\left(\bigcap_{s=0}^{r} J\left(\gamma_{i_{s}}\right)\right) \\
& =\sum_{r=0}^{N(Q)-1}(-1)^{r} \sum_{1 \leq j_{1}<\cdots<j_{r} \leq N(Q)}^{\substack{r}} \sum_{\substack{i, q_{i+j} \geq m, 0 \leq s \leq r}} \mu\left(\bigcap_{s=0}^{r} J\left(\gamma_{\left.i+j_{s}\right)}\right)\right)
\end{aligned}
$$

where $j_{0}=0$. Denote for simplicity

$$
\mu_{j_{1}, \ldots, j_{r}}=\sum_{\substack{i, q_{i+j_{s}} \geq m, 0 \leq s \leq r}} \mu\left(\bigcap_{s=0}^{r} J\left(\gamma_{i+j_{s}}\right)\right) .
$$

Many of these terms vanish by Lemma 3. More precisely,

$$
\begin{equation*}
\mu(S(m, \alpha, c))=\sum_{r=0}^{K}(-1)^{r} \sum_{1 \leq j_{1}<\cdots<j_{r} \leq K} \mu_{j_{1}, \ldots, j_{r}} . \tag{5}
\end{equation*}
$$

Then by Lemma 4, one can further write $\mu_{j_{1}, \ldots, j_{r}}$ as a finite sum,

$$
\begin{equation*}
\mu_{j_{1}, j_{2}, \ldots, j_{r}}=\sum_{1 \leq k_{1}, k_{2}, \ldots, k_{j_{r}} \leq T} \mu_{j_{1}, j_{2}, \ldots, j_{r}}^{k_{1}, k_{2}, \ldots, k_{j}}, \tag{6}
\end{equation*}
$$

where

$$
\begin{equation*}
\mu_{j_{1}, j_{2}, \ldots, j_{r}}^{k_{1}, k_{2}, \ldots, k_{j}}=\sum_{\substack{i, v_{Q}\left(\gamma_{i+j}\right)=k_{j}, 1 \leq j \leq j_{r}, q_{i+j} \geq m, 0 \leq s \leq r}} \mu\left(\bigcap_{s=0}^{r} J\left(\gamma_{i+j_{s}}\right)\right) . \tag{7}
\end{equation*}
$$

For any integer $n>0$ and any positive integers $k_{1}, k_{2}, \ldots, k_{n}$, let

$$
\mathscr{T}_{k_{1}, \ldots, k_{n}}=\bigcap^{n} T^{-j+1} \mathscr{T}_{k_{j}} .
$$

Then for any $(x, y) \in \mathscr{T}_{k_{1}, \ldots, k_{n}}$, we have

$$
L_{0}(x, y)=x, \quad L_{1}(x, y)=y
$$

and recursively,

$$
L_{i+1}(x, y)=k_{i} L_{i}(x, y)-L_{i-1}(x, y), \quad 1 \leq i \leq n
$$

Therefore there exist real numbers $\omega_{i}, v_{i}$ depending only on $k_{1}, \ldots, k_{n}$ such that

$$
L_{i}(x, y)=\omega_{i} x+v_{i} y, \quad 0 \leq i \leq n+1
$$

The set $\mathscr{T}_{k_{1}, \ldots, k_{n}} \subset \mathscr{T}$ is obtained by intersecting finitely many half planes, and so it is a convex polygon. For any $t>0$ and any $1 \leq j_{1}<j_{2} \cdots<j_{s} \leq$ $n$, define the set

$$
\mathscr{H}_{k_{1}, k_{2}, \ldots, k_{n}}^{j_{1}, j_{2}, \ldots, j_{s}}(t)=\left\{(x, y) \in \mathscr{T}_{k_{1}, k_{2}, \ldots, k_{n}}: L_{j_{v}}(x, y) \geq t, 0 \leq v \leq s\right\}
$$

Here $\mathscr{H}_{k_{1}, \ldots, k_{n}}^{j_{1}, \ldots, j_{s}}(t)$ is also a convex polygon. We now return to (7). For any $\gamma_{i}, \gamma_{i+1} \in \mathscr{F}_{Q}$, we see that

$$
\begin{gathered}
v_{Q}\left(\gamma_{i+1}\right)=k_{1}, v_{Q}\left(\gamma_{i+2}\right)=k_{2}, \ldots, v_{Q}\left(\gamma_{i+j_{r}}\right)=k_{j_{r}} \\
q_{i} \geq m, q_{i+j_{1}} \geq m, q_{i+j_{2}} \geq m, \ldots, q_{i+j_{r}} \geq m
\end{gathered}
$$

This means that

$$
\begin{aligned}
& \left(\frac{q_{i}}{Q}, \frac{q_{i+1}}{Q}\right) \in \mathscr{T}_{k_{1}, k_{2}, \ldots, k_{j_{r}}} \\
& Q L_{j_{v}}\left(\frac{q_{i}}{Q}, \frac{q_{i+1}}{Q}\right) \geq m, \quad 0 \leq v \leq r
\end{aligned}
$$

that is,

$$
\left(\frac{q_{i}}{Q}, \frac{q_{i+1}}{Q}\right) \in \mathscr{H}_{k_{1}, \ldots, k_{j_{r}}}^{j_{1}, \ldots, j_{r}}\left(\frac{m}{Q}\right),
$$

and therefore (7) becomes

$$
\begin{equation*}
\mu_{j_{1}, j_{2}, \ldots, j_{r}}^{k_{1}, k_{2}, \ldots, k_{j r}}=\sum_{\substack{i,\left(\frac{q_{i}}{Q}, \frac{q_{i+1}}{Q}\right) \in \mathscr{H}_{k_{1}, \ldots, k_{j_{r}}}^{j_{1}, \ldots, r_{r}}\left(\frac{m}{Q}\right)}} \mu\left(\bigcap_{s=0}^{r} J\left(\gamma_{i+j_{s}}\right)\right) . \tag{8}
\end{equation*}
$$

Next, fix $j_{1}, \ldots, j_{r}, k_{1}, \ldots, k_{j_{r}}$, and denote for simplicity $\mathscr{H}_{k_{1}, \ldots, k_{j_{r}}}^{j_{1}, \ldots, j_{r}}$ by $\mathscr{H}$. For any $t>0$ and $\left(\frac{q_{i}}{Q}, \frac{q_{i+1}}{Q}\right) \in \mathscr{H}(t)$,
$\mu\left(\bigcap_{s=0}^{r} J\left(\gamma_{i+j_{s}}\right)\right)=\max \left\{0, \min _{0 \leq s \leq r}\left\{\frac{a_{i+j_{s}}}{q_{i+j_{s}}}+\frac{\alpha}{q_{i+j_{s}}^{2}}\right\}-\max _{0 \leq s \leq r}\left\{\frac{a_{i+j_{s}}}{q_{i+j_{s}}}-\frac{\alpha}{q_{i+j_{s}}^{2}}\right\}\right\}$.
Since for any $0 \leq j_{s^{\prime}}<j_{s} \leq j_{r}$,

$$
\frac{a_{i+j_{s}}}{q_{i+j_{s}}}-\frac{a_{i+j_{s^{\prime}}}}{q_{i+j_{s^{\prime}}}}=\sum_{\lambda=0}^{j_{s}-j_{s^{\prime}}-1} \frac{1}{q_{i+j_{s}-\lambda} q_{i+j_{s}-\lambda-1}},
$$

and

$$
q_{i+j_{s}}=Q L_{j_{s}}\left(\frac{q_{i}}{Q}, \frac{q_{i+1}}{Q}\right)=Q\left(\omega_{j_{s}} \frac{q_{i}}{Q}+v_{j_{s}} \frac{q_{i+1}}{Q}\right)
$$

where $\omega_{j_{s}}, v_{j_{s}}$ are real numbers which only depend on $k_{1}, k_{2}, \ldots, k_{j_{r}}$, one sees that the measure $\mu\left(\bigcap_{s=0}^{r} J\left(\gamma_{i+j_{s}}\right)\right)$, when considered as a function of the variables $q_{i}, q_{i+1}$, is piecewise smooth. Denote this function by $f_{j_{1}, \ldots, j_{r}}(x, y)$, so that

$$
f_{j_{1}, \ldots, j_{r}}\left(q_{i}, q_{i+1}\right)=\mu\left(\bigcap_{s=0}^{r} J\left(\gamma_{i+j_{s}}\right)\right)
$$

Here

$$
Q^{2} f_{j_{1}, \ldots, j_{r}}(Q x, Q y)=f_{j_{1}, \ldots, j_{r}}(x, y)
$$

and for any $t$ such that $t>\delta>0$, one has

$$
\left|\left\lvert\, f_{j_{1}, \ldots, j_{r}}\left\|_{\infty, Q \mathscr{H}(t)}<_{\alpha, \delta} \frac{1}{Q^{2}}, \quad\right\| D f_{j_{1}, \ldots, j_{r}}\right. \|_{\infty, Q \mathscr{H}(t)}<_{\alpha, \delta} \frac{1}{Q^{3}} .\right.
$$

Given $\epsilon>0$, there exists an $M>0$, such that if $m>M$, then $1 / c \leq$ $m / Q \leq 1 / c+\epsilon$, and $\mathscr{H}(1 / c+\epsilon) \subset \mathscr{H}(m / Q) \subset \mathscr{H}(1 / c)$. The set $\mathscr{H}(1 / c)$ is a convex polygon, and $f_{j_{1}, \ldots, j_{r}}$ is piecewise smooth. By Lemma 1 ,

$$
\begin{aligned}
\sum_{\substack{i,\left(\frac{q_{i}}{Q}, \frac{q_{i+1}}{Q}\right) \in \mathscr{H}(1 / c)}} \mu\left(\bigcap_{s=0}^{r} J\left(\gamma_{i+j_{s}}\right)\right) & =\sum_{\substack{i,\left(\frac{q_{i}}{Q}, \frac{q_{i+1}}{Q}\right) \in \mathscr{H}(1 / c)}} f_{j_{1}, \ldots, j_{r}}\left(q_{i}, q_{i+1}\right) \\
& =\sum_{(u, v) \in Q \mathscr{H}(1 / c) \cap \mathbb{Z}_{p r}^{2}} f_{j_{1}, \ldots, j_{r}}(u, v) \\
& =\frac{6}{\pi^{2}} \iint_{Q \mathscr{H}(1 / c)} f_{j_{1}, \ldots, j_{r}}(x, y) \mathrm{d} x \mathrm{~d} y+E_{1} \\
& =\frac{6 Q^{2}}{\pi^{2}} \iint_{\mathscr{H}(1 / c)} f_{j_{1}, \ldots, j_{r}}(Q x, Q y) \mathrm{d} x \mathrm{~d} y+E_{1} \\
& =\frac{6}{\pi^{2}} \iint_{\mathscr{H}(1 / c)} f_{j_{1}, \ldots, j_{r}}(x, y) \mathrm{d} x \mathrm{~d} y+E_{1},
\end{aligned}
$$

where

$$
\begin{aligned}
E_{1} & \ll\left\|f_{j_{1}, \ldots, j_{r}}\right\|_{\infty, Q \mathscr{H}(1 / c)} Q \log Q+\left\|D f_{j_{1}, \ldots, j_{r}}\right\|_{\infty, Q \mathscr{H}(1 / c)} \text { Area }(Q \mathscr{H}(1 / c)) \log Q \\
& \ll \alpha, c \frac{Q \log Q}{Q^{2}}+\frac{Q^{2} \log Q}{Q^{3}}<_{\alpha, c} \frac{\log Q}{Q}
\end{aligned}
$$

here we use

$$
\operatorname{Area}(Q \mathscr{H}(1 / c))=Q^{2} \operatorname{Area}(\mathscr{H}(1 / c)) \ll Q^{2}
$$

Similarly,

$$
\sum_{\substack{i,\left(\frac{q_{i}}{Q}, \frac{q_{i+1}}{Q}\right) \in \mathscr{H}(1 / c+\epsilon)}} \mu\left(\bigcap_{s=0}^{r} J\left(\gamma_{i+j_{s}}\right)\right)=\frac{6}{\pi^{2}} \iint_{\mathscr{H}(1 / c+\epsilon)} f_{j_{1}, \ldots, j_{r}}(x, y) \mathrm{d} x \mathrm{~d} y+E_{2},
$$

where we also have

$$
E_{2}<_{\alpha, c} \frac{\log Q}{\square}
$$

Clearly,

$$
\iint_{\mathscr{H}(1 / c+\epsilon)} f_{j_{1}, \ldots, j_{r}}(x, y) \mathrm{d} x \mathrm{~d} y=\iint_{\mathscr{H}(1 / c)} f_{j_{1}, \ldots, j_{r}}(x, y) \mathrm{d} x \mathrm{~d} y+o(1),
$$

as $\epsilon \rightarrow 0$. Letting $m \rightarrow \infty$ and $\epsilon \rightarrow 0$, we conclude that

$$
\begin{equation*}
\lim _{m \rightarrow \infty} \mu_{j_{1}, j_{2}, \ldots, j_{r}}^{k_{1}, k_{2}, \ldots, k_{j}}=\frac{6}{\pi^{2}} \iint_{\mathscr{H}_{k_{1}, k_{2}, \ldots, k_{j}}^{j_{1}, j_{2}, \ldots, j_{r}}(1 / c)} f_{j_{1}, j_{2}, \ldots, j_{r}}(x, y) \mathrm{d} x \mathrm{~d} y \tag{9}
\end{equation*}
$$

for any $1 \leq j_{1}<j_{2}<\ldots<j_{r} \leq K$ and $1 \leq k_{1}, k_{2}, \ldots, k_{j_{r}} \leq T$. By (6),

$$
\begin{aligned}
\lim _{m \rightarrow \infty} \mu_{j_{1}, j_{2}, \ldots, j_{r}} & =\frac{6}{\pi^{2}} \sum_{1 \leq k_{1}, k_{2}, \ldots, k_{j_{r}} \leq T} \iint_{\mathscr{H}_{k_{1}, k_{2}, \ldots, k_{j}}^{j_{1}, j_{2}, \ldots, j_{r}}(1 / c)} f_{j_{1}, j_{2}, \ldots, j_{r}}(x, y) \mathrm{d} x \mathrm{~d} y \\
& =\frac{6}{\pi^{2}} \iint_{\mathscr{H}^{j_{1}, j_{2}, \ldots, j_{r}}(1 / c)} f_{j_{1}, j_{2}, \ldots, j_{r}}(x, y) \mathrm{d} x \mathrm{~d} y
\end{aligned}
$$

where

$$
\begin{aligned}
\mathscr{H}^{j_{1}, j_{2}, \ldots, j_{r}}(t) & =\bigcup_{1 \leq k_{1}, k_{2}, \ldots, k_{j_{r}} \leq T} \mathscr{H}_{k_{1}, k_{2}, \ldots, k_{j_{r}}}^{j_{1}, j_{2}, \ldots, j_{r}}(t) \\
& =\left\{(x, y) \in \mathscr{T}: L_{j_{v}}(x, y) \geq t, 0 \leq v \leq r\right\} .
\end{aligned}
$$

Lastly, from (5) it follows that the $\operatorname{limit}^{\lim } \lim _{m \rightarrow \infty} \mu(S(m, \alpha, c))$ exists for any $\alpha>0, c \geq 1$. Therefore we have proved:

Theorem 2. The limit (2) exists for any $\alpha>0, c \geq 1$. Denoting the limit by $\rho(\alpha, c)$, we have

$$
\begin{equation*}
\rho(\alpha, c)=\frac{6}{\pi^{2}} \sum_{r=0}^{K}(-1)^{r} \sum_{1 \leq j_{1}<\cdots<j_{r} \leq K} \iint_{\mathscr{H} j_{1}, \ldots, j_{r}(1 / c)} f_{j_{1}, \ldots, j_{r}}(x, y) \mathrm{d} x \mathrm{~d} y . \tag{10}
\end{equation*}
$$

We end this section with some comments on how to derive explicit formulas such as (1),(3) and (4) from the equation (10) above. Let us take the case $\alpha \leq c /\left(1+c^{2}\right)$ first. As Erdös, Szüsz and Turán remarked in [7], $J\left(\gamma_{i}\right) \bigcap J\left(\gamma_{j}\right)=\Phi$ for any $i \neq j$. Hence $K=0$, and only the first term survives in (10). More precisely,

$$
\rho(\alpha, c)=\frac{6}{\pi^{2}} \iint_{\mathscr{H}(1 / c)} f(x, y) \mathrm{d} x \mathrm{~d} y
$$

where $\mathscr{H}(1 / c)=\left\{(x, y) \in \mathscr{T}: L_{0}(x, y)=x \geq 1 / c\right\}$ and $f(x, y)=\frac{2 \alpha}{x^{2}}$, so

$$
\rho(\alpha, c)=\frac{6}{\pi^{2}} \iint_{\mathscr{H}(1 / c)} f(x, y) \mathrm{d} x \mathrm{~d} y=\frac{12 \alpha}{\pi^{2}} \log c .
$$

This is (1). In the case $c^{2} /\left(1+c^{2}\right) \leq \alpha c \leq 1$, Kesten observed in [20] that $J\left(\gamma_{i}\right) \bigcap J\left(\gamma_{i+2}\right)=\Phi$ for any $i$. Therefore $K=1$, and only the first two terms are left. Then

$$
\begin{equation*}
\rho(\alpha, c)=\frac{6}{\pi^{2}} \iint \quad f(x, y) \mathrm{d} x \mathrm{~d} y-\frac{6}{\pi^{2}} \iint \quad f_{1}(x, y) \mathrm{d} x \mathrm{~d} y . \tag{11}
\end{equation*}
$$

The first term is already computed and equals $\frac{12 \alpha}{\pi^{2}} \log c$. As for the second one, $\mathscr{H}^{1}(1 / c)=\{(x, y) \in \mathscr{T}: x \geq 1 / c, y \geq 1 / c\}$ and

$$
f(x, y)=\max \left\{0, \frac{\alpha}{x^{2}}+\frac{\alpha}{y^{2}}-\frac{1}{x y}\right\}
$$

Note that if $1 / 2 \leq \alpha \leq 1 / c$, we always have $f(x, y)=\frac{\alpha}{x^{2}}+\frac{\alpha}{y^{2}}-\frac{1}{x y} \geq 0$, and one finds that

$$
\begin{equation*}
\iint_{\mathscr{H}^{1}(1 / c)} f_{1}(x, y) \mathrm{d} x \mathrm{~d} y=2\left(\alpha c-2 \alpha+\frac{\alpha}{c}-\frac{1}{2}(\log c)^{2}\right) . \tag{12}
\end{equation*}
$$

In the case $c /\left(1+c^{2}\right) \leq \alpha \leq \min (1 / 2,1 / c)$, Kesten pointed out that $f(x, y) \geq 0$ if any only if $1 / \beta \leq x / y \leq \beta$, where

$$
\beta=\frac{1+\left(1-4 \alpha^{2}\right)^{1 / 2}}{2 \alpha}
$$

A straightforward computation shows that $\beta \leq c \leq \beta+1$, which further gives
$\iint_{\mathscr{H}^{1}(1 / c)} f_{1}(x, y) \mathrm{d} x \mathrm{~d} y=2\left(\alpha c+\frac{\alpha}{c}-\alpha \beta-\frac{\alpha}{\beta}+\alpha\left(\frac{1}{\beta}-\beta\right) \log \frac{c}{\beta}-\frac{1}{2}\left(\log \frac{c}{\beta}\right)^{2}\right)$.
Plugging this and (12) into (11) will yield the formulas (4) and (3) immediately.

## 5. Proof of Theorem 1

Let $\mathbf{I}=(a, b) \subset[0,1]$. We use the same notation as in the previous section. Denote $\mathscr{F}_{Q}(\mathbf{I})=\mathscr{F}_{Q} \bigcap \mathbf{I}$ and consider the set

$$
S_{\mathbf{I}}^{\prime}(m, \alpha, c)=\bigcup_{\gamma_{i} \in \mathscr{F}_{Q}(\mathbf{I}) ; q_{i} \geq m} J\left(\gamma_{i}\right)
$$

where as before, $Q=[m c]$. For any $\epsilon>0$, there exists an $M>0$ such that if $m>M$, then

$$
\begin{equation*}
S_{\mathbf{I}_{\epsilon}}^{\prime}(m, \alpha, c) \subset S_{\mathbf{I}}(m, \alpha, c) \subset S_{\mathbf{I}}^{\prime}(m, \alpha, c) \tag{13}
\end{equation*}
$$

where $\mathbf{I}_{\epsilon}:=(a+\epsilon, b-\epsilon)$. Let us first consider the measure of the right hand side of (13). As in the proof of Theorem 2, one finds that

$$
\begin{equation*}
\mu\left(S_{\mathbf{I}}^{\prime}(m, \alpha, c)\right)=\sum^{K}(-1)^{r} \quad \sum \quad \mu_{j_{1}, \ldots, j_{r}} \tag{14}
\end{equation*}
$$

where

$$
\begin{aligned}
\mu_{j_{1}, \ldots, j_{r}} & =\sum_{\substack{i, q_{i}+j_{s} \geq m, 0 \leq s \leq r, \gamma_{j} \in \mathbf{I}, 0 \leq s \leq r}} f_{j_{1}, \ldots, j_{r}}\left(q_{i}, q_{i+1}\right) \\
& =\sum_{\substack{i, q_{i} \leq j_{s} \geq m, 0 \leq s \leq r, \gamma_{i} \in \mathbf{I}}} f_{j_{1}, \ldots, j_{r}}\left(q_{i}, q_{i+1}\right)-\sum_{\substack{i, q_{i} \leq j_{s} \geq m, 0 \leq s \leq r, \gamma_{i} \in \mathbf{I}, \gamma_{j} \notin \mathbf{I}}} f_{j_{1}, \ldots, j_{r}}\left(q_{i}, q_{i+1}\right) \\
& =\mu_{j_{1}, \ldots, j_{r}}^{\prime}-e_{j_{1}, \ldots, j_{r}} .
\end{aligned}
$$

It is clear that

$$
e_{j_{1}, \ldots, j_{r}} \leq j_{r} \frac{2 \alpha}{m^{2}} \leq \frac{2 K \alpha}{m^{2}}<_{\alpha, c} \frac{1}{Q^{2}}
$$

We further write

$$
\begin{equation*}
\mu_{j_{1}, j_{2}, \ldots, j_{r}}^{\prime}=\sum_{1 \leq k_{1}, k_{2}, \ldots, k_{j r} \leq T} \mu_{j_{1}, j_{2}, \ldots, j_{r}}^{k_{1}, k_{2}, \ldots, k_{j_{r}}} \tag{15}
\end{equation*}
$$

where

$$
\begin{equation*}
\mu_{j_{1}, j_{2}, \ldots, j_{r}}^{\prime k_{1}, k_{2}, \ldots, k_{j_{r}}}=\sum_{\substack{i, v_{Q}\left(\gamma_{i+j}\right)=k_{j}, 1 \leq j \leq j_{r}, q_{i+j} \leq m, 0 \leq s \leq r, \gamma_{i} \in \mathbf{I}}} f_{j_{1}, j_{2}, \ldots, j_{r}}\left(q_{i}, q_{i+1}\right) . \tag{16}
\end{equation*}
$$

For any two consecutive Farey fractions $\gamma_{i}=a_{i} / q_{i}<\gamma_{i+1}=a_{i+1} / q_{i+1}$, $a_{i+1} q_{i}-a_{i} q_{i+1}=1$, we have $a_{i} \equiv-\bar{q}_{i+1}\left(\bmod q_{i}\right)$, where $\bar{q}_{i+1}$ is uniquely defined by the relations $1 \leq \bar{q}_{i+1} \leq q_{i}$ and $q_{i+1} \bar{q}_{i+1} \equiv 1\left(\bmod q_{i}\right)$. Since $1 \leq a_{i} \leq q_{i}$, we have $a_{i}=q_{i}-\bar{q}_{i+1}$ and

$$
\gamma_{i}=\frac{a_{i}}{q_{i}}=1-\frac{\bar{q}_{i+1}}{q_{i}} \in \mathbf{I}
$$

so $\bar{q}_{i+1} \in \mathbf{I}_{q_{i}}$, where $\mathbf{I}_{q_{i}}=\left((1-b) q_{i},(1-a) q_{i}\right)$. Therefore (16) becomes

$$
\begin{equation*}
\mu_{j_{1}, j_{2}, \ldots, j_{r}}^{\prime k_{1}, k_{2}, \ldots, k_{j_{r}}}=\sum_{\substack{i,\left(\frac{q_{i}}{Q}, \frac{q_{i+1}}{Q}\right) \in \mathscr{H}_{k_{1}}^{j_{1}, k_{2}, \ldots, k_{r}} \\ \bar{q}_{i+1} \in \mathbf{I}_{q_{i}}, k_{j_{r}}}} f_{j_{1}, j_{2}, \ldots, j_{r}}\left(q_{i}, q_{i+1}\right) . \tag{17}
\end{equation*}
$$

Fix now $j_{1}, \ldots, j_{r}, k_{1}, \ldots, k_{j_{r}}$ and write $\mathscr{H}$ for $\mathscr{H}_{k_{1}, k_{2}, \ldots, k_{j_{r}}}^{j_{1}, j_{2}, \ldots, j_{r}}$. By Lemma 2,

$$
\begin{aligned}
\sum_{\substack{\left.i, \frac{q_{i+1}}{Q}\right) \in \mathscr{H}(1 / c),}} f_{j_{1}, \ldots, j_{r}}\left(q_{i}, q_{i+1}\right) & =\sum_{\substack{(u, v) \in Q \mathscr{H}(1 / c) \cap \mathbb{Z}_{p r}^{2}, \gamma_{i} \in \mathbf{I}}} f_{j_{1}, \ldots, j_{r}}(a, b) \\
& =\frac{6|\mathbf{I}|}{\pi^{2}} \iint_{Q \mathscr{H}(1 / c)} f_{j_{1}, \ldots, j_{r}}(x, y) \mathrm{d} x \mathrm{~d} y+E_{1}^{\prime} \\
& =\frac{6|\mathbf{I}|}{\sim^{2}} \iint f_{j_{1}, \ldots, j_{r}}(x, y) \mathrm{d} x \mathrm{~d} y+E_{1}^{\prime},
\end{aligned}
$$

where

$$
\begin{gathered}
E_{1}^{\prime}<\delta_{\delta} m_{f}\left\|f_{j_{1}, \ldots, j_{r}}\right\|_{\infty, Q \mathscr{H}(1 / c)} Q^{\frac{3}{2}+\delta}+\left\|f_{j_{1}, \ldots, j_{r}}\right\|_{\infty, Q \mathscr{H}(1 / c)} Q \log Q \\
+\left\|D f_{j_{1}, \ldots, j_{r}}\right\|_{\infty, Q \mathscr{H}(1 / c)} \operatorname{Area}(Q \mathscr{H}(1 / c)) \log Q
\end{gathered}
$$

for any $\delta>0$. Here $m_{f}$ is an upper bound for the number of intervals of monotonicity of each of the functions $y \mapsto f_{j_{1}, \ldots, j_{r}}(x, y)$, which are piecewise smooth for any $1 \leq j_{1}<\cdots<j_{r} \leq K$. Hence $m_{f}<_{\alpha, c} 1$. We have seen in the previous section that

$$
\left\|f_{j_{1}, \ldots, j_{r}}\right\|_{\infty, Q \mathscr{H}(1 / c)}<_{\alpha, c} \frac{1}{Q^{2}}, \quad\left\|D f_{j_{1}, \ldots, j_{r}}\right\|_{\infty, Q \mathscr{H}(1 / c)}<_{\alpha, c} \frac{1}{Q^{3}}
$$

and

$$
\text { Area }\left(Q \mathscr{H}(1 / c) \ll Q^{2} .\right.
$$

Putting together all the above estimates, we derive for $0<\delta<1 / 2$,

$$
E_{1}^{\prime} \lll \alpha, c, \delta \frac{m_{f} Q^{\frac{3}{2}+\delta}}{Q^{2}}+\frac{Q \log Q}{Q^{2}}+\frac{Q^{2} \log Q}{Q^{3}} \ll_{\alpha, c, \delta} \frac{1}{Q^{1 / 2-\delta}}
$$

Choose $\delta=1 / 3$ and let $m \rightarrow \infty$. Since $\lim _{m \rightarrow \infty} \frac{m}{Q}=\frac{1}{c}$, we obtain as in the proof of Theorem 2 that

$$
\begin{aligned}
& \lim _{m \rightarrow \infty} \mu_{j_{1}, j_{2}, \ldots, j_{r}}^{\prime k_{1}, k_{2}, \ldots, k_{j_{r}}}=\lim _{m \rightarrow \infty} \sum_{i,} f_{j_{1}, j_{2}, \ldots, j_{r}}\left(q_{i}, q_{i+1}\right) \\
& \left(\frac{q_{i}, q_{i+1}}{Q}, \frac{q_{i+1}}{Q}\right) \in \mathscr{H}_{k_{1}, k_{1}, \ldots, k_{2}, k_{j_{r}}}^{j_{1}, j_{2}, \ldots, j_{r}}\left(\frac{m}{Q}\right), \\
& =\lim _{m \rightarrow \infty} \sum_{i,} f_{j_{1}, j_{2}, \ldots, j_{r}}\left(q_{i}, q_{i+1}\right) \\
& \left(\frac{q_{i}, q_{i+1}}{Q}, \frac{q_{i}+1}{Q}\right) \in \mathscr{H}_{k_{1}, k_{1}, k_{2}, \ldots, j_{2}, k_{r}}^{\bar{q}_{j}}(1 / c), \\
& =\frac{6|\mathbf{I}|}{\pi^{2}} \iint_{\mathscr{H}_{k_{1}, k_{2}, \ldots, k_{j_{r}}}^{j_{1}, j_{2}, \ldots, j_{r}}(1 / c)} f_{j_{1}, j_{2}, \ldots, j_{r}}(x, y) \mathrm{d} x \mathrm{~d} y .
\end{aligned}
$$

By combining (14), (15) and (10) we deduce that

$$
\begin{aligned}
\lim _{m \rightarrow \infty} \mu\left(S_{\mathbf{I}}^{\prime}(m, \alpha, c)\right) & =\frac{6|\mathbf{I}|}{\pi^{2}} \sum_{1 \leq j_{1}<\cdots<j_{r} \leq K}(-1)^{r} \iint_{\mathscr{H} j_{1}, \ldots, j_{r}(1 / c)} f_{j_{1}, \ldots, j_{r}}(x, y) \mathrm{d} x \mathrm{~d} y \\
& =|\mathbf{I}| \cdot \rho(\alpha, c)
\end{aligned}
$$

where

$$
\rho(\alpha, c)=\lim _{m \rightarrow \infty} \mu(S(m, \alpha, c))
$$

and for any $t>0$,

$$
\mathscr{H}^{j_{1}, \ldots, j_{r}}(t)=\bigcup_{1 \leq k_{1}, \ldots, k_{j_{r}} \leq T} \mathscr{H}_{k_{1}, \ldots, k_{j_{r}}}^{j_{1}, \ldots, j_{r}}(t)
$$

Similarly,

Lastly, by letting $\epsilon \rightarrow 0$, we conclude from (13) that the $\operatorname{limit}^{\lim } \lim _{m \rightarrow \infty} \mu\left(S_{\mathbf{I}}(m, \alpha, c)\right)$ exists for any $\alpha>0, c \geq 1$ and moreover,

$$
\lim _{m \rightarrow \infty} \mu\left(S_{\mathbf{I}}(m, \alpha, c)\right)=|\mathbf{I}| \cdot \rho(\alpha, c),
$$

which completes the proof of Theorem 1.
