LIPSCHITZ EQUIVALENCE OF CANTOR SETS AND ALGEBRAIC PROPERTIES OF CONTRACTION RATIOS

HUI RAO, HUO-JUN RUAN, AND YANG WANG

Abstract. In this paper we investigate the Lipschitz equivalence of dust-like self-similar sets in \( \mathbb{R}^d \). One of the fundamental results by Falconer and Marsh [On the Lipschitz equivalence of Cantor sets, *Mathematika*, 39 (1992), 223–233] establishes conditions for Lipschitz equivalence based on the algebraic properties of the contraction ratios of the self-similar sets. In this paper we extend the study by examining deeper such connections.

A key ingredient of our study is the introduction of a new equivalent relation between two dust-like self-similar sets called matchable condition. Thanks to a certain measure-preserving property of bi-Lipschitz maps between dust-like self-similar sets, we show that the matchable condition is a necessary condition for Lipschitz equivalence.

Using the matchable condition we prove several conditions on the Lipschitz equivalence of dust-like self-similar sets based on the algebraic properties of the contraction ratios, which include a complete characterization of Lipschitz equivalence when the multiplication groups generated by the contraction ratios have full rank. We also completely characterize the Lipschitz equivalence of dust-like self-similar sets with two branches (i.e. they are generated by IFS with two contractive similarities). Some other results are also presented, including a complete characterization of Lipschitz equivalence when one of the self-similar sets has uniform contraction ratio.

1. Introduction

Let \( E, F \) be compact sets in \( \mathbb{R}^d \). We say that \( E \) and \( F \) are *Lipschitz equivalent*, and denote it by \( E \sim F \), if there exists a bijection \( \psi : E \to F \) which is *bi-Lipschitz*, i.e. there exists a constant \( C > 0 \) such that

\[
C^{-1}|x - y| \leq |\psi(x) - \psi(y)| \leq C|x - y|
\]

for all \( x, y \in E \).

An area of interest in the study of self-similar sets is the Lipschitz equivalence property. With Lipschitz equivalence many important properties of a self-similar set are preserved. Cooper and Pignataro [1] studied the case when \( E, F \subset [0, 1] \) and \( \psi \) is order-preserving. Falconer and Marsh [5, 6] studied quasi-circles and dust-like self-similar sets. In the book of David and Semmes [2], several problems...
Let there exist positive integers $\rho_1, \ldots, \rho_m \in (0, 1)$ with $\sum_{j=1}^{m} \rho_j^d < 1$. We say that the attractor $F$ of any IFS is the unique nonempty compact set $F$ satisfying $F = \bigcup_{j=1}^{m} \phi_j(F)$, see [8]. We say that the attractor $F$ is dust-like, or alternatively, the IFS $\{\phi_j\}$ satisfies the strong separation condition (SSC), if the sets $\{\phi_j(F)\}$ are disjoint. It is well known that if $F$ is dust-like then the Hausdorff dimension $s = \dim_H(F)$ of $F$ satisfies $\sum_{j=1}^{m} \rho_j^d = 1$.

Now for any $\rho_1, \ldots, \rho_m \in (0, 1)$ with $\sum_{j=1}^{m} \rho_j^d < 1$ we will call $\rho = (\rho_1, \ldots, \rho_m)$ a contraction vector, and use the notation $D(\rho) = D(\rho_1, \ldots, \rho_m)$ to denote the set of all dust-like self-similar sets that are the attractor of some IFS with contraction ratios $\rho_j, j = 1, \ldots, m$ on $\mathbb{R}^d$. (Throughout the paper the dimension $d$ will be implicit.) Clearly all sets in $D(\rho)$ have the same Hausdorff dimension, which we denote by $s = \dim_H(D(\rho))$. We are less concerned with the translation part of the IFS’s because of the following result, see e.g. [11]:

**Proposition 1.1.** Let $E, F \in D(\rho_1, \ldots, \rho_m)$. Then $E$ and $F$ are Lipschitz equivalent.

Let $\rho = (\rho_1, \ldots, \rho_m)$ and $\tau = (\tau_1, \ldots, \tau_n)$ be two contraction vectors. According to Proposition 1.1, we give the following definition: We say $D(\rho)$ and $D(\tau)$ are Lipschitz equivalent, and denote it by $D(\rho) \sim D(\tau)$, if $E \sim F$ for some (and thus for all) $E \in D(\rho)$ and $F \in D(\tau)$. Note that if $\tau$ is a permutation of $\rho$ then we clearly have $D(\tau) = D(\rho)$. One of the most fundamental results in the study of Lipschitz equivalence is the following theorem, proved by Falconer and Marsh [6], that establishes a connection to the algebraic properties of the contraction ratios:

**Theorem 1.2** ([6], Theorem 3.3). Let $D(\rho)$ and $D(\tau)$ be Lipschitz equivalent, where $\rho = (\rho_1, \ldots, \rho_m)$ and $\tau = (\tau_1, \ldots, \tau_n)$ are two contraction vectors. Let $s = \dim_H(D(\rho)) = \dim_H(D(\tau))$. Then

1. $Q(\rho_1, \ldots, \rho_m) = Q(\tau_1, \ldots, \tau_n)$, where $Q(a_1, \ldots, a_m)$ denotes the subfield of $\mathbb{R}$ generated by $\mathbb{Q}$ and $a_1, \ldots, a_m$.
2. There exist positive integers $p, q$ such that

$$\text{sgp}(\rho_1^p, \ldots, \rho_m^p) \subseteq \text{sgp}(\tau_1^q, \ldots, \tau_n^q), \quad \text{sgp}(\rho_1, \ldots, \rho_m) \subseteq \text{sgp}(\tau_1, \ldots, \tau_n),$$

where $\text{sgp}(a_1, \ldots, a_m)$ denotes the subsemigroup of $(\mathbb{R}^+ \times)$ generated by $a_1, \ldots, a_m$.

Using this theorem, it was shown in [6] that there exist dust-like self-similar sets $E$ and $F$ such that $\dim_H E = \dim_H F$ but $E$ and $F$ are not Lipschitz equivalent. Also, from this theorem, the following question arises naturally:

---

One referee told us that Jang-Mei Wu at the University of Illinois at Urbana-Champaign also solved the $\{1, 3, 4\} = 1, 4, 5$ problem years ago without publishing.
Can we present nontrivial sufficient conditions and necessary conditions on $\rho$ and $\tau$ such that $D(\rho) \sim D(\tau)$?

Since the above work by Falconer and Marsh, there have been little progress in this direction as we know of. The present paper does not give a complete answer to Question 1, which is likely to be extremely hard. It does, however, answer the question in several important special cases that should allow us to gain some deep insight into the problem.

In [6] Falconer and Marsh had developed several techniques to study the Lipschitz equivalence of dust-like self-similar sets. These techniques allowed them to prove Theorem 1.2 and other important results (see also Lemma 2.1 and 2.3 and Remark 2.5). Recently some other techniques have been developed. One that will prove Theorem 1.2 and other important results (see also Lemma 2.1 and 2.3 and Remark 2.5). Recently some other techniques have been developed. One that will prove Theorem 1.2 and other important results.

Other conditions on Lipschitz equivalence of self-similar sets have been established, e.g. in Xi and Ruan [18] and in Xi [15]. In both studies, sufficient and necessary conditions for Lipschitz equivalence have been established in terms of graph-directed sets. However, these conditions are difficult to check. Generally, given two contraction vectors $\rho = (\rho_1, \rho_2, \ldots, \rho_m)$ and $\tau = (\tau_1, \tau_2, \ldots, \tau_n)$, it is not practical to apply these conditions to decide whether $D(\rho)$ and $D(\tau)$ are Lipschitz equivalent, even for the two-branch case $m = n = 2$.

In this paper we introduce the notion of rank for a contraction vector $\rho = (\rho_1, \ldots, \rho_m)$. Let $\langle \rho_1, \ldots, \rho_m \rangle$ denote the subgroup of $(\mathbb{R}^+, \times)$ generated by $\rho_1, \ldots, \rho_m$, then it is a free abelian group. It follows that $\langle \rho_1, \ldots, \rho_m \rangle$ has a nonempty basis and we can define the rank of $\langle \rho_1, \ldots, \rho_m \rangle$, which we denote by $\text{rank}(\rho)$, to be the cardinality of the basis. Clearly $1 \leq \text{rank}(\rho) \leq m$. In case that $\text{rank}(\rho) = m$, we say $\rho$ has full rank. For rank of a free abelian group see e.g. [7].

According to Theorem 1.2 (2), if $D(\rho) \sim D(\tau)$, then $\text{rank}(\rho) = \text{rank}(\tau) = \text{rank}(\rho, \tau)$, where $(\rho, \tau) := \langle \rho_1, \ldots, \rho_m, \tau_1, \ldots, \tau_n \rangle$ for $\rho = (\rho_1, \ldots, \rho_m)$ and $\tau = (\tau_1, \ldots, \tau_n)$. One of our main theorems is:

**Theorem 1.3.** Let $\rho = (\rho_1, \ldots, \rho_m)$ and $\tau = (\tau_1, \ldots, \tau_n)$ be two contraction vectors such that $\text{rank}(\rho) = m$. Then $D(\rho)$ and $D(\tau)$ are Lipschitz equivalent if and only if $\tau$ is a permutation of $\rho$.

Theorem 1.3 and a result on the irreducibility of certain trinomials by Ljunggren [9] allows us to completely characterize the Lipschitz equivalence of dust-like self-similar sets with two branches. We prove:

**Theorem 1.4.** Let $(\rho_1, \rho_2)$ and $(\tau_1, \tau_2)$ be two contraction vectors with $\rho_1 \leq \rho_2$, $\tau_1 \leq \tau_2$. Assume that $\rho_1 \leq \tau_1$. Then $D(\rho) \sim D(\tau)$ if and only if one of the two conditions holds:

1. $\rho_1 = \tau_1$ and $\rho_2 = \tau_2$.
2. There exists a real number $0 < \lambda < 1$, such that $$(\rho_1, \rho_2) = (\lambda^5, \lambda) \quad \text{and} \quad (\tau_1, \tau_2) = (\lambda^3, \lambda^2).$$
Another case where the Lipschitz equivalence of dust-like self-similar sets can be characterized completely is when one of them has uniform contraction ratio.

**Theorem 1.5.** Let \( \rho = (\rho_1, \cdots, \rho_m) = (\rho, \ldots, \rho) \) and \( \tau = (\tau_1, \ldots, \tau_n) \). Then \( D(\rho) \) and \( D(\tau) \) are Lipschitz equivalent if and only if the following conditions hold:

1. \( \dim_H D(\tau) = \dim_H D(\rho) = \log m / \log \rho - 1 \).
2. There exists a \( q \in \mathbb{Z}^+ \) such that \( m^{1/q} \in \mathbb{Z} \) and \( \frac{\log \tau_j}{\log \rho} \in \mathbb{Z} / q\mathbb{Z} \) for all \( j = 1, 2, \ldots, n \).

As an application of Theorem 1.4, we can see that the conditions in Theorem 1.2 are necessary but not sufficient via the following example.

**Example 1.1.** Let \( x, y \), \( 0 < x, y < 1 \), be the solution of the equations

\[
x^6 + y^4 = 1 \quad \text{and} \quad x^3 + y^4 = 1.
\]

One can easily check that the solution indeed exists. Let \( s \) be a real number such that \( 0 < s < 1 \). Suppose that the contraction vectors of \( E \) and \( F \) are \( (x^6/s, y^4/s) \) and \( (x^3/s, y^4/s) \), respectively. Then \( E \) and \( F \) have the same Hausdorff dimension and satisfy the conditions in Theorem 1.2. However, \( E \) and \( F \) are not Lipschitz equivalent by Theorem 1.4.

To prove Theorem 1.3 in this paper we shall introduce a new equivalent relation between two dust-like self-similar sets, which is referred to as the *matchable* condition. The matchable condition is somewhat technical so we shall defer its definition to the next section. We prove a refinement of condition (2) in Theorem 1.2 involving the matchable condition:

**Theorem 1.6.** Let \( E \) and \( F \) be two dust-like self-similar sets. If \( E \sim F \), then \( E \) and \( F \) are matchable.

The paper is organized as follows: In Section 2, we review some important results in [6, 18] concerning the Lipschitz equivalence of dust-like self-similar sets, and prove Theorem 1.6. In Section 3, we prove Theorem 1.3. In Section 4, we focus on two-branch self-similar sets and prove Theorem 1.4. Finally in Section 5 we prove Theorem 1.5.

2. A NEW CRITERION FOR LIPSCHITZ EQUIVALENCE

2.1. Measure-preserving property. We first introduce some notations. Let \( E \) be the attractor of the IFS \( \Phi = \{\phi_1, \ldots, \phi_m\} \). Let \( \Sigma_m^* := \bigcup_{i=1}^\infty \{1,2,\ldots,m\}^i \). For any word \( i = i_1 \cdots i_k \in \Sigma_m \), we call \( k \) the length of the word \( i \) and denote it by \( |i| \). Furthermore, a cylinder \( E_i \) is defined to be \( E_i = \phi_i(E) := \phi_{i_1} \circ \cdots \circ \phi_{i_k}(E) \).

In this section we consider the Lipschitz equivalence of two dust-like self-similar sets \( E \) and \( F \) with the following setup: We assume that \( E \) is the attractor of \( \Phi = \{\phi_1, \ldots, \phi_m\} \) with contraction vector \( \rho = (\rho_1, \ldots, \rho_m) \) and \( F \) is the attractor of \( \Psi = \{\psi_1, \ldots, \psi_n\} \) with contraction vector \( \tau = (\tau_1, \ldots, \tau_n) \). We also assume in subsections 2.1 and 2.2 that \( s = \dim_H E = \dim_H F \) and \( f : E \longrightarrow F \) is a bi-Lipschitz map.

The following lemma is fundamental.
Lemma 2.1 ([6]). There exists an integer $n_0$ such that for any $i \in \Sigma^*$, there exist $k, j_1, \ldots, j_p \in \Sigma^*$ such that $F_{k,j_1}, \ldots, F_{k,j_p}$ are disjoint and

$$f(E_i) = \bigcup_{r=1}^{p} F_{k,j_r} \subset F_k,$$

where each $|j_r| \leq n_0$. In particular $\mathcal{H}^s(f(E_i)) = \mathcal{H}^s(F_k) \sum_{r=1}^{p} (\tau_{j_r})^s$.

Remark 2.2. It is clear that we can require each $|j_r| = n_0$ in the above lemma. And, under this restriction, $k$ is unique if we require $\kappa$ to have the maximal length. Consequently the set $\{j_1, \ldots, j_p\}$ is also uniquely determined by $i$. We will write $p_i$ for $p$ if necessary. We call this unique decomposition to be the maximum decomposition of $f(E_i)$ with respect to $F$ and $n_0$. From now on, we fix $n_0$ in this section. We remark that $p$ in (2.1) is bounded since $p \leq n_0$.

In [6], Falconer and Marsh introduced a function $g_k : E \rightarrow \mathbb{R}$ defined by

$$g_k(x) = \frac{\mathcal{H}^s(f(E_i))}{\mathcal{H}^s(E_i)}$$

for $x \in E_i$, where $i \in \{1, \ldots, m\}^k$. We shall abuse the notation by writing $g_k(E_i) = \frac{\mathcal{H}^s(f(E_i))}{\mathcal{H}^s(E_i)}$. It is easy to show that

$$g_k(E_i) = \sum_{i=1}^{m} \frac{\mathcal{H}^s(E_{i,j})}{\mathcal{H}^s(E_i)} g_{k+1}(E_{i,j}).$$

Lemma 2.3 ([6]). The set $\{ \frac{g_{k+1}(x)}{g_k(x)} : x \in E, k \geq 1 \}$ is finite.

Xi and Ruan obtained the following property. We include a short proof for completeness.

Lemma 2.4 ([18]). There is a cylinder $E_{i_0}$ and a constant $c > 0$ such that $g_k(x) = c$ for all $x \in E_{i_0}$ and $k \geq |i_0|$.

Proof. Set $T = \sup_{k \geq 1} \max_{|i|=k} g_k(E_i)$. Since $f$ is bi-Lipschitz, we have $T < +\infty$.

If $\frac{g_{k+1}(x)}{g_k(x)} = 1$ for all $x \in E$ and all $k \geq 1$, then the lemma clearly holds. Otherwise set $\delta = \min \left( \left\{ \frac{g_{k+1}(x)}{g_k(x)} - 1 : x \in E, k \geq 1 \right\} \setminus \{0\} \right)$. Then $\delta > 0$ by Lemma 2.3. Choose $i_0$ such that (denote $\ell = |i_0|$)

$$g_k(E_{i_0}) > T/(1 + \delta).$$

Then $\frac{g_{k+1}(E_{i_0})}{\mathcal{H}^s(E_{i_0})} < 1 + \delta$ for all $j$ and hence $\frac{g_{k+1}(E_{i_0})}{\mathcal{H}^s(E_{i_0})} < 1$ by the definition of $\delta$.

Now formula (2.3) implies that $\frac{g_{k+1}(E_{i_0})}{\mathcal{H}^s(E_{i_0})} = 1$ for all $j$. Hence each $E_{i_0j}$ satisfies (2.4) and we can repeat the same argument with $E_{i_0j}$ in place of $E_{i_0}$. Set $c = g_l(E_{i_0})$ and the lemma is proved. \qed

This lemma means that the restriction of $f$ on $E_{i_0}$ is measure-preserving up to a constant. More precisely for any Borel set $A \subset E_{i_0}$ we have

$$\frac{\mathcal{H}^s(f(A))}{\mathcal{H}^s(A)} = c = \frac{\mathcal{H}^s(f(E_{i_0}))}{\mathcal{H}^s(E_{i_0})}.$$
Remark 2.5. To prove Theorem 1.2, one needs the fact that \( g_k \) converges on a set with positive Hausdorff measure \( \mathcal{H}^s \). [6] showed that \( g_k(x) \) converges for \( \mathcal{H}^s \)-almost all \( x \in E \) by using the martingale convergence theorem. Lemma 2.4 says that \( g_k(x) \) converges on a cylinder of \( E \) and hence provides an alternative proof of Theorem 1.2.

We shall call the cylinder \( E_{ki} \) in Lemma 2.4 a stable cylinder with respect to the map \( f \). From now on, we fix a stable cylinder \( E_{ki} \) in this section. Going back to Lemma 2.1 and Remark 2.2, for any \( i \in \Sigma_m \), there is a (unique) maximum decomposition of \( f(E_{ki}) \) with respect to \( F \) and \( n_0 \):

\[
f(E_{ki}) = \bigcup_{r=1}^{p_{ki}} F_{kr},
\]

where \( |j_r| = n_0 \). The following observation is crucial for the proof of our new criterion.

Lemma 2.6. The set \( \mathcal{M} = \bigcup_{i \in \Sigma_m} \left\{ \frac{\mathcal{H}^s(E_{ki})}{\mathcal{H}^s(F_{ki})} : 1 \leq r \leq p_{ki} \right\} \) is finite. Consequently, the sets

\[
\mathcal{M}' = \bigcup_{i \in \Sigma_m} \left\{ \frac{\text{diam} E_{ki}}{\text{diam} F_{ki}} : 1 \leq r \leq p_{ki} \right\} \quad \text{and} \quad \mathcal{M}'' = \bigcup_{i \in \Sigma_m} \left\{ \frac{p_{ki}}{\tau_{kj}} : 1 \leq r \leq p_{ki} \right\}
\]

are finite.

Proof. Note that

\[
\frac{\mathcal{H}^s(E_{ki})}{\mathcal{H}^s(F_{ki})} = \frac{\mathcal{H}^s(E_{ki})}{\sum_{j=1}^{p_{ki}} \mathcal{H}^s(F_{kj})} \cdot \frac{\sum_{j=1}^{p_{ki}} \mathcal{H}^s(F_{kj})}{\mathcal{H}^s(F_{ki})} = \frac{1}{c} \sum_{j=1}^{p_{ki}} \frac{\mathcal{H}^s(F_{kj})}{\mathcal{H}^s(F_{ki})} = \frac{1}{c} \sum_{j=1}^{p_{ki}} \tau_{kj}.
\]

The last expression can take only finite many values, since \( p_{ki} \leq n_0^d \) and each \( \tau_{kj} \) can take on only finitely many distinct values. It follows that \( \mathcal{M} \) is a finite set.

Since \( \frac{\mathcal{H}^s(E_{ki})}{\mathcal{H}^s(F_{ki})} = c_0 \cdot \left( \frac{\text{diam} E_{ki}}{\text{diam} F_{ki}} \right)^s \), where \( c_0 = \frac{\mathcal{H}^s(E)}{\mathcal{H}^s(F)} \cdot \left( \frac{\text{diam} F}{\text{diam} F} \right)^s \) is a constant only dependent on \( E \) and \( F \), we know that \( \mathcal{M}' \) is a finite set. It follows from \( \frac{p_{ki}}{\tau_{kj}} = \frac{\text{diam} E_{ki}}{\text{diam} F_{ki}} \cdot \frac{\text{diam} F}{\text{diam} F} \) that \( \mathcal{M}'' \) is also a finite set. \( \square \)

2.2. New criterion. Let \( \rho \) and \( \tau \) be the contraction vectors in the above subsection. We call \( w_1, \ldots, w_L \) a pseudo-basis of \( V = \langle \rho, \tau \rangle \) if \( L = \text{rank } V \) and \( \langle w_1, \ldots, w_L \rangle \supseteq V \). It is clear that a basis of \( V \) is natural to be a pseudo-basis. For any \( x_1, x_2 \in V \), we define their distance with respect to the pseudo-basis \( w_1, \ldots, w_L \) by

\[
h(x_1, x_2) := \left( \sum_{j=1}^{L} (s_j - t_j)^2 \right)^{1/2},
\]

where \( s_j, t_j \in \mathbb{Z} \) are the unique integers such that \( x_1 = \prod_{j=1}^{L} w_{s_j}^j, \quad x_2 = \prod_{j=1}^{L} w_{t_j}^j \).

It is easy to show that if \( h_1 \) and \( h_2 \) are two distances on \( V \) defined as above, then they are comparable, i.e., there exists a constant \( C \geq 1 \) such that

\[
C^{-1} h_1(x_1, x_2) \leq h_2(x_1, x_2) \leq Ch_1(x_1, x_2), \quad \forall x_1, x_2 \in V.
\]

Hence, we fix the pseudo-basis and the function \( h \) from now on.
For any two positive numbers \( \rho_{\text{max}} = \max\{\rho_1, \ldots, \rho_m\} \) and \( \rho_{\text{min}} = \min\{\rho_1, \ldots, \rho_m\} \). For any \( t \in (0, 1) \) let
\[
\mathcal{W}(E, t) := \{ i \in \Sigma_c^* : \rho_i \leq t < \rho_{i+1} \},
\]
where \( i^* \) is the word obtained by deleting the last letter of \( i \), i.e. \( i^* = i_1 \cdots i_{k-1} \) if \( i = i_1 \cdots i_k \). We define \( \rho_0 = 1 \) if the length of \( i \) equals 1. Similarly, we may define \( \mathcal{W}(F, t) \) with respect to its contraction vector \( \tau \). We remark that \( \mathcal{W}(E, t) \) has been used in other studies on self-similar sets (e.g. [8, 13]).

Pick some \( i \in \Sigma_c^* \). There is a (unique) maximum decomposition of \( f(E_i) \) with respect to \( F \) and \( n_0 \):
\[
f(E_i) = \bigcup_{p=1}^{n_0} F_{kj}^p,
\]
where \( |j| = n_0 \). We define a relation \( \mathcal{R}(i, t, f) \subset \mathcal{W}(E, t) \times \mathcal{W}(F, t) \) by
\[
(2.7) \quad \mathcal{R}(i, t, f) := \left\{ (i', j') \in \mathcal{W}(E, t) \times \mathcal{W}(F, t) : f(E_i) \cap \bigcup_{p=1}^{n_0} F_{kj}^p \neq \emptyset \right\}.
\]

We need the following geometrical lemma to prove our criterion. Note that \( F \) is dust-like, \( F \) satisfies the open set condition, i.e., there exists an open set \( V \), such that \( V \supset \bigcup_{i=1}^{n_0} \psi_i(V) \) and \( \psi_i(V) \cap \psi_j(V) = \emptyset \) for distinct \( i, j \). Thus, using the method in [13], we can easily see that the following lemma holds (For detailed proof, please see Appendix A).

**Lemma 2.7.** For any two positive numbers \( c_1, c_2 \) with \( c_1 \leq c_2 \), there exists a constant \( c_3 > 0 \), such that for any nonempty subset \( A \) of \( \mathbb{R}^d \), \( A \) can intersect at most \( c_3 \) mutually disjoint cylinders \( F_i \) with \( c_1 \text{diam} A \leq \text{diam} F_i \leq c_2 \text{diam} A \).

Now we can prove our criterion.

**Theorem 2.8.** Assume that \( f : E \rightarrow F \) is bi-Lipschitz and \( i_0 \in \Sigma_c^* \) is a stable cylinder. Let \( h \) be a distance on \( V = (\rho, \tau) \) defined by (2.6). Then there exists a constant \( M_0 > 0 \) such that for any \( t \in (0, 1) \) we have

1. For any \( i \in \mathcal{W}(E, t) \),
\[
(2.8) \quad 1 \leq \text{card} \{ j : (i, j) \in \mathcal{R}(i_0, t, f) \} \leq M_0.
\]

Similarly, for any \( j \in \mathcal{W}(F, t) \),
\[
(2.9) \quad 1 \leq \text{card} \{ i : (i, j) \in \mathcal{R}(i_0, t, f) \} \leq M_0.
\]

2. If \( (i, j) \in \mathcal{R}(i_0, t, f) \) then \( h(\rho_i, \tau_j) \leq M_0 \).

**Proof.** Let \( f(E_{i_0}) = \bigcup_{p=1}^{n_0} F_{kj}^p \) be the (unique) maximum decomposition of \( f(E_{i_0}) \) with respect to \( F \) and \( n_0 \), where \( |j| = n_0 \) and \( p = p_{i_0} \).

Fix \( t \in (0, 1) \). Then
\[
E = \{ E_{i_0} : i \in \mathcal{W}(E, t) \} \quad \text{and} \quad F = \{ F_{kj}^p : 1 \leq r \leq p, j \in \mathcal{W}(F, t) \}
\]
is a partition of \( E_{i_0} \) and \( f(E_{i_0}) \), respectively, since
\[
\bigcup_{i \in \mathcal{W}(E, t)} f(E_{i_0}) = \bigcup_{r=1}^{p} F_{kj}^p = \bigcup_{j \in \mathcal{W}(F, t)} \bigcup_{r=1}^{p} F_{kj}^p = f(E_{i_0}) = \bigcup_{r=1}^{p} F_{kj}^p.
\]

By symmetry, in order to prove (1) it suffices to prove (2.8). The left hand side inequality is obvious since for any \( E_{i_0} \in E \), \( f(E_{i_0}) \) intersects at least one element of \( F \).
To prove the right hand side inequality of (2.8), we first show that the size of $E_{k,i}$ and $F_{kj,j}$ are comparable. Indeed, $\frac{\text{diam } E_{k,i}}{\text{diam } F_{kj,j}} = \frac{\rho_{k,i}}{\tau_{kj,j}}$. Since $\{i_0, k_1, \ldots, k_p\}$ is fixed, we know that $\frac{1}{\tau_{kj,j}}$ takes values from a finite set. Meanwhile $\rho_{\min} \leq \frac{\rho_{i}}{\tau_{j}} \leq \frac{1}{\tau_{\min}}$ by the definition of $W(E, t)$ and $W(F, t)$. Thus, there exists a constant $C_0 > 0$ such that

$$C_0^{-1} < \frac{\text{diam } E_{k,i}}{\text{diam } F_{kj,j}} < C_0. \tag{2.9}$$

Combining (2.9) with the bi-Lipschitz property of $f$, we know that there exists a constant $C_1 > 0$ such that $C_1^{-1} < \frac{\text{diam } f(E_{k,i})}{\text{diam } F_{kj,j}} < C_1$. By Lemma 2.7, the number of such $F_{kj,j}$ which intersects $f(E_{k,i})$ is bounded by a constant $M_0$ dependent on $C_1$, the dimension $d$ of the space and the IFS $\{\psi_i\}_{i=1}^n$. In other words,

$$\max_{i \in W(E, t)} \text{card } \{j : (i, j) \in R(i_0, t, f)\} < M_0.$$

We now complete the proof by proving (2). Suppose $(i,j) \in R(i_0, t, f)$, then by definition there exists an $r \in \{1, \ldots, p\}$ such that $f(E_{k,i}) \cap F_{kj,j} \neq \emptyset$. Let us fix this $F_{kj,j}$ for the discussions below.

Let $f(E_{k,i}) = \bigcup_{t=1}^{p} F_{kj_{t},j_{t}}$ be the maximum decomposition of $f(E_{k,i})$ with respect to $F$ and $n_0$, where $|j_{t}| = n_0$. Then there is a $t$ such that $F_{kj_{t},j_{t}} \cap F_{kj,j} \neq \emptyset$. Since $F_{kj_{t},j_{t}}$ and $F_{kj,j}$ are all cylinders, we have

$$F_{kj_{t},j_{t}} \subset F_{kj,j} \quad \text{or} \quad F_{kj,j} \subset F_{kj_{t},j_{t}}. \tag{2.10}$$

Notice that

$$\frac{\rho_{t}}{\tau_{j_{t}}} = \frac{\rho_{k,i}}{\tau_{kj,j}} \cdot \frac{\tau_{kj,j}}{\tau_{kj_{t},j_{t}}} = \frac{\rho_{k,i}}{\tau_{kj_{t},j_{t}}} \cdot \frac{\tau_{kj_{t},j_{t}}}{\tau_{kj,j}} \cdot \frac{\tau_{kj,j}}{\tau_{kj_{t},j_{t}}} \cdot \frac{\tau_{kj_{t},j_{t}}}{\rho_{t}}.$$

By Lemma 2.6, we know that $\frac{\rho_{k,i}}{\tau_{kj_{t},j_{t}}}$ takes values from a finite set $M''$. On the other hand, $\frac{\tau_{kj,j}}{\rho_{t}}$ takes only finitely many values since $\{i_0, k_1, \ldots, k_p\}$ is fixed. Thus, in order to prove (2), it suffices to prove that $\frac{\tau_{kj_{t},j_{t}}}{\rho_{t}}$ belongs to a finite set.

By Lemma 2.6, $\frac{\text{diam } E_{k,i}}{\text{diam } F_{kj,j}}$ take values from a finite set $M'$. Combining this with (2.9), we know that $\frac{\text{diam } F_{kj,j}}{\text{diam } F_{kj_{t},j_{t}}}$ are comparable. Thus, using (2.10), we obtain that $\frac{\tau_{kj_{t},j_{t}}}{\rho_{t}}$ belongs to a finite set so that $\frac{\tau_{kj_{t},j_{t}}}{\rho_{t}}$ belongs to a finite set.

\[\square\]

2.3. Matchable condition. Let $E$ and $F$ be two dust-like self-similar sets with contraction vectors $\rho$ and $\tau$ respectively. Let $h$ be a distance on $V = (\rho, \tau)$ defined by (2.6).

Let $M_0$ be a constant. For $t \in (0, 1)$, a relation $R \subset W(E, t) \times W(F, t)$ is said to be $(M_0, h)$-matchable, or simply $M_0$-matchable if there is no confusion, if

(i) $1 \leq \text{card } \{j : (i, j) \in R\} \leq M_0$ for any $i \in W(E, t)$, and $1 \leq \text{card } \{i : (i, j) \in R\} \leq M_0$ for any $j \in W(F, t)$.

(ii) If $(i,j) \in R$, then $h(\rho_i, \tau_j) \leq M_0$.

We also say that $W(E, t)$ and $W(F, t)$ are $(M_0, h)$-matchable, or $M_0$-matchable, if there exists a $(M_0, h)$-matchable relation $R \subset W(E, t) \times W(F, t)$. 

Definition 2.9. We shall call two self-similar sets $E$ and $F$ are matchable, if there exists a constant $M_0$ such that for any $t \in (0,1)$, $W(E,t)$ and $W(F,t)$ are $M_0$-matchable.

We remark that the matchable property does not depend on the choice of pseudo-basis of $(\rho, \tau)$.

The proof of Theorem 2.8, which states that if $E \sim F$ then $E$ and $F$ are matchable, follows immediately that Theorem 1.6 holds.

3. Self-similar sets with full algebraic rank

For each contraction vector $\rho = (\rho_1, \ldots, \rho_m)$ we had defined rank$(\rho)$ to be the cardinality of the basis of the multiplication subgroup generated by $\{\rho_j\}$. We shall define the algebraic rank of any $E \in \mathcal{D}(\rho)$ to be rank$(\rho)$. When the algebraic rank is $m$ we say that $E$ and $\mathcal{D}(\rho)$ have full algebraic rank. By Theorem 1.2 if two dust-like self-similar sets $E$ and $F$ are Lipschitz equivalent then they must have the same algebraic rank.

Lemma 3.1. Let $\rho = (\rho_1, \ldots, \rho_m)$ and $\tau = (\tau_1, \ldots, \tau_m)$ be two contraction vectors such that rank$(\rho)$ = rank$(\tau)$ = $m$. If $\mathcal{D}(\rho) \sim \mathcal{D}(\tau)$, then there exist $\lambda_j \in \mathbb{R}^+$, $p_j \in \mathbb{Z}^+$, $q_j \in \mathbb{Z}^+$, $1 \leq j \leq m$, and a permutation $\kappa$ on $\{1, \ldots, m\}$, such that $\rho_j = \lambda_j^{p_j}$, $\tau_j = \lambda_{\kappa(j)}^{q_{\kappa(j)}}$, $1 \leq j \leq m$.

Proof. By Theorem 1.2 (2), there exists an integer $p > 0$ such that $\tau_1, \ldots, \tau_m$ belong to the semigroup generated by $\rho_1^{1/p}, \ldots, \rho_m^{1/p}$. Denote $\rho_j^{1/p}$ by $\lambda_j$ for each $j$. Then $\lambda_1, \ldots, \lambda_m$ is a pseudo-basis of $V = \langle \rho, \tau \rangle$. Let $h$ be the distance on $V$ with respect to this pseudo-basis. Let $a_{ji}$, $1 \leq i, j \leq m$, be non-negative integers such that $\ln \tau_j = a_{j1} \ln \lambda_1 + \cdots + a_{jm} \ln \lambda_m$. Fix $1 \leq i \leq m$. We assert that there exists at least one $j$, $1 \leq j \leq m$, such that $\ln \lambda_j$ is a power of $\lambda_i$, in other words, $\ln \lambda_j$ is an integral multiple of $\ln \lambda_i$.

Without loss of generality, we assume that $i = 1$. Suppose $\ln \lambda_j$ is not integral multiple of $\ln \lambda_1$ for all $1 \leq j \leq m$. This means that $(a_{j1}, \ldots, a_{jm})$ does not have the form $(a, 0, \ldots, 0)$.

$E \sim F$ implies that there exists $M_0 > 0$, such that $W(E, t)$ and $W(F, t)$ are $(M_0, h)$-matchable for any $t \in (0,1)$. Let $i = 1^k = 1 \cdots 1$ be an element of $W(E, t)$. Then there exists $j \in W(F, t)$ such that $h(\rho_i, \tau_j) < M_0$. Suppose that the occurrence of the letter $j$ in $j$ is $c_j$, $1 \leq j \leq m$. Then

$$
\ln \lambda_j = \sum_{i=1}^{m} \left( \sum_{j=1}^{m} c_j a_{ji} \right) \ln \lambda_i.
$$

Since $\ln \rho_i = kp \ln \lambda_1$, we have

$$
h(\rho_i, \tau_j) \geq \max \left\{ \sum_{j=1}^{m} c_j a_{ji} : 2 \leq i \leq m \right\}.
$$

Pick any $j \in \{1, \ldots, m\}$. Since $(a_{j1}, \ldots, a_{jm})$ does not have the form $(a, 0, \ldots, 0)$, there exists at least one $i \in \{2, \ldots, m\}$ such that $a_{ji} \geq 1$. Thus $\sum_{j=1}^{m} c_j a_{ji} \geq c_j$. By the arbitrary of $j$, we have $M_0 > h(\rho_i, \tau_j) \geq \max_{j=1}^{m} c_j$. However, $\max c_j$ tends to infinity when $t$ tends to 0. This is a contradiction. Hence our assertion holds.
Therefore, for any \(1 \leq i \leq m\), there exists at least one \(j\) such that \(\ln \tau_j = q_i \ln \lambda_i\). Moreover, this \(j = j(i)\) is unique since \(\text{rank} (\rho) = \text{rank} (\tau) = m\). Let \(\kappa\) be the permutation of \(1, \ldots, m\) which sends \(j\) to \(i\), then we have \(\ln \tau_j = q_{\kappa(j)} \ln \lambda_{\kappa(j)}\).

Set \(p_j = p\) for \(1 \leq j \leq m\), we obtain the lemma. \(\square\)

**Lemma 3.3.** Let \(m\) be a given positive integer and \(G\) the function defined by
\[
G(x_1, \ldots, x_m) = \left(\frac{x_1 + \cdots + x_m}{x_1}\right)^{x_1} \cdots \left(\frac{x_1 + \cdots + x_m}{x_m}\right)^{x_m},
\]
where \(x_1, \ldots, x_m \in \mathbb{R}^+\). Assume that \(a_1, \ldots, a_m\) are positive real numbers such that
\[
G(a_1x_1, \ldots, a_mx_m) = \left(\frac{a_1x_1 + a_2x_2}{a_1x_1}\right)^{a_1x_1} \cdots \left(\frac{a_1x_1 + a_2x_2}{a_2x_2}\right)^{a_2x_2}.
\]
holds for any positive vectors \((x_1, \ldots, x_m)\). Then \(a_1 = \cdots = a_m = 1\).

**Proof.** By the continuity of \(G\), we know that (3.2) holds for any positive vectors \((x_1, \ldots, x_m)\). For given \(x_1, x_2 \in \mathbb{R}^+\) let \(x_j \to 0^+\) for any \(j \geq 3\). It follows from \(\lim_{x^+ = 1} x^+ = 1\) and (3.2) that
\[
\left(\frac{x_1 + x_2}{x_1}\right)^{x_1} = \left(\frac{x_1 + x_2}{x_2}\right)^{x_2} = \left(\frac{a_1x_1 + a_2x_2}{a_1x_1}\right)^{a_1x_1} \left(\frac{a_1x_1 + a_2x_2}{a_2x_2}\right)^{a_2x_2}.
\]
Now we fix \(x_2 \in \mathbb{R}^+\) and let \(x_1 \to +\infty\). Then \(\left(\frac{x_1 + x_2}{x_1}\right)^{x_1}\) and \(\left(\frac{a_1x_1 + a_2x_2}{a_1x_1}\right)^{a_1x_1}\) converge to \(e^{x_2}\) and \(e^{a_2x_2}\), respectively. On the other hand, as \(x_1 \to +\infty\) we have
\[
\left(\frac{x_1 + x_2}{x_2}\right)^{x_2} = O(x_1^{x_2}), \quad \left(\frac{a_1x_1 + a_2x_2}{a_2x_2}\right)^{a_2x_2} = O(x_1^{a_2x_2}).
\]
The equality (3.3) now implies \(a_2 = 1\). By symmetry we also have all \(a_j = 1\), proving the lemma. \(\square\)

**Lemma 3.3.** Let \(\rho = (\rho_1, \ldots, \rho_m)\) and \(\tau = (\tau_1, \ldots, \tau_m)\) be two contraction vectors, where for each \(j\), \(\rho_j = \lambda_j^{p_j}\) and \(\tau_j = \lambda_j^{q_j}\) for some \(\lambda_j > 0\) and \(p_j, q_j \in \mathbb{Z}^+\). Assume that \(\log \lambda_1, \ldots, \log \lambda_m\) are linearly independent over \(\mathbb{Q}\). Then \(D(\rho)\) and \(D(\tau)\) are Lipschitz equivalent if and only if \(\rho = \tau\).

**Proof.** Clearly all we need is to prove the only if part. Assume that \(D(\rho) \sim D(\tau)\). Let \(E \in D(\rho)\), \(F \in D(\tau)\). Let \(h\) be the distance on \(V = \langle \rho, \tau \rangle\) with respect to the pseudo-basis \(\lambda_1, \ldots, \lambda_m\). \(E \sim F\) implies that \(E\) and \(F\) are \((M_0, h)\)-matchable for some \(M_0 > 0\). Using the matchable property we will prove that \(p_j = q_j\) for \(1 \leq j \leq m\).

Given positive integers \(A_1, \ldots, A_m\). Set \(t = \prod_{j=1}^m \lambda_j^{p_j A_j}\), and define \(I = \{i \in \Sigma_m : \rho_i = t\}\). Then \(I \subset \mathcal{W}(E, t)\) and the cardinality of \(I\) is
\[
K(A_1, \ldots, A_m) := \text{card} I = \frac{(A_1 + \cdots + A_m)!}{A_1! \cdots A_m!}.
\]
Let \(\mathcal{R}_t\) be an \(M_0\)-matchable relation between \(\mathcal{W}(E, t)\) and \(\mathcal{W}(F, t)\). Let \(\mathcal{J}\) be the set of elements \(j\) in \(\mathcal{W}(F, t)\) such that \(\{i \in I : (i, j) \in \mathcal{R}_t\} \neq \emptyset\). Then \(\text{card} \mathcal{J} \geq M_0^{-1} \text{card} I\). Hence
\[
\text{card} \{j \in \mathcal{W}(F, t) : h(t, \tau_j) \leq M_0\} \geq \text{card} \mathcal{J} \geq M_0^{-1} K(A_1, \ldots, A_m).
\]
By the assumption, \( \tau_j \) has the form \( \tau_j = \prod_{j=1}^{m} \lambda_j^{B_j} \), where \( B_j \) are non-negative integers. So \( j \in J \) implies that \( h(t, \tau_j) \leq M_0 \) and thus \( |p_j A_j - q_j B_j| \leq M_0 \) for \( 1 \leq j \leq m \). Therefore,

\[
\sum_{(B_1, \ldots, B_m)} \frac{(B_1 + \cdots + B_m)!}{B_1! \cdots B_m!} \geq \text{card } J \geq M_0^{-1}K(A_1, \ldots, A_m),
\]

where \( (B_1, \ldots, B_m) \) runs over positive integer vectors satisfying \( |p_j A_j - q_j B_j| \leq M_0 \) for \( 1 \leq j \leq m \).

Let \( C \) be an integer constant such that \( |B_j - \frac{p_j}{q_j} A_j| < \frac{M_0}{q_j} < C, 1 \leq j \leq m \). Set \( a_j = p_j/q_j \) for \( 1 \leq j \leq m \). Then the terms on the left hand side of (3.4) have

\[
\frac{(B_1 + \cdots + B_m)!}{B_1! \cdots B_m!} K^{-1}(a_1 A_1, \ldots, a_m A_m)
\]

\[
\leq \left( \frac{p_1}{q_1} A_1 + \cdots + \frac{p_m}{q_m} A_m + mC \right)! \left( \frac{p_1}{q_1} A_1 + \cdots + \frac{p_m}{q_m} A_m \right)! \left( \frac{p_1}{q_1} A_1 + \cdots + \frac{p_m}{q_m} A_m + 1 \right)\prod_{j=1}^{m} \left( \frac{p_j}{q_j} A_j - C + 1 \right).
\]

Let \( (x_1, \ldots, x_m) \in \mathbb{Q}^m \) be a positive rational vector. Set \( A_j = x_j q_n \) where \( q \) is chosen so that all \( qx_j/q_j, q x_j/p_j \) are integers. Then the left hand side of (3.4) contains at most \( (2C + 1)^m \) terms and each term in the sum is not bigger than \( P(n)K(a_1 A_1, \ldots, a_m A_m) \) where \( P(n) \) is the polynomial

\[
P(n) = (Ln + mC) \cdots (Ln + 1) \prod_{j=1}^{m} (a_j x_j q_n) \cdots (a_j x_j q_n - C + 1),
\]

where \( L = (a_1 x_1 + \cdots + a_m x_m)q \). Hence by (3.4),

\[
(2C + 1)^m P(n)K(a_1 x_1 q_n, \ldots, a_m x_m q_n) \geq M_0^{-1}K(x_1 q_n, \ldots, x_m q_n),
\]

and therefore

\[
K(x_1 q_n, \ldots, x_m q_n) \leq M_0(2C + 1)^m P(n).
\]

Similarly, let \( C' \) be an integer constant such that \( |A_j - \frac{p_j}{q_j} B_j| < \frac{M_0}{q_j} < C', 1 \leq j \leq m \). Set \( b_j = a_j^{-1} = q_j/p_j, y_j = x_j a_j \) and \( B_j = y_j q_n \) for \( 1 \leq j \leq m \). Then \( B_j = x_j p_j q_n/q_j \) are all integers. Also, \( b_j y_j q_n = x_j q_n = A_j \) are all integers. Using Theorem 2.8 and by the same method for proving (3.5), we obtain

\[
K(y_1 q_n, \ldots, y_m q_n) \leq M_0(2C' + 1)^m Q(n),
\]

where \( Q(n) \) is a polynomial determined by \( p_j, q_j, x_j, q \) and \( C' \). It follows from (3.5) and (3.6) that

\[
\frac{1}{M_0(2C' + 1)^m Q(n)} \leq \frac{K(x_1 q_n, \ldots, x_m q_n)}{K(a_1 x_1 q_n, \ldots, a_m x_m q_n)} \leq M_0(2C + 1)^m P(n).
\]
Now Stirling’s formula asserts that
\[ n! = \sqrt{2\pi n} \left( \frac{n}{e} \right)^n e^{\frac{\alpha(n)}{2n}}. \quad 0 < \theta(n) < 1. \]

Denote \( \theta(x_1 q_n + \cdots + x_m q_n), \theta(x_i q_n), \theta(a_1 x_1 q_n + \cdots + a_m x_m q_n) \) and \( \theta(a_i x_i q_n) \) by \( \alpha_n, \alpha_{i,n}, \beta_n \) and \( \beta_{i,n}, 1 \leq i \leq m \), respectively. We have
\[
\frac{K(x_1 q_n, \ldots, x_m q_n)}{K(a_1 x_1 q_n, \ldots, a_m x_m q_n)} = \sqrt{\frac{(x_1 + \cdots + x_m) a_1 \cdots a_m}{a_1 x_1 + \cdots + a_m x_m}} e^{\xi_n} \left( \frac{G(x_1, \ldots, x_m)}{G(a_1 x_1, \ldots, a_m x_m)} \right)^{q_n},
\]
where \( G \) is defined by (3.1) and
\[
\xi_n = \frac{1}{12 q_n} \left\{ \frac{\alpha_n}{x_1 + \cdots + x_m} - \sum_{i=1}^{m} \frac{\alpha_{i,n}}{x_i} - \frac{\beta_n}{a_1 x_1 + \cdots + a_m x_m} + \sum_{i=1}^{m} \frac{\beta_{i,n}}{a_i x_i} \right\}.
\]
Clearly, for fixed positive rational numbers \( a_i, x_i, 1 \leq i \leq m \) and fixed positive integer \( q \), we have \(-1 < \xi_n < 1\) if \( n \) is large enough. Thus, there exist two positive constants \( c_1, c_2 \) depending only on \( a_i, x_i, 1 \leq i \leq m \) and \( q \) such that
\[
(3.8) \quad \frac{K(x_1 q_n, \ldots, x_m q_n)}{K(a_1 x_1 q_n, \ldots, a_m x_m q_n)} = T_n \cdot \left( \frac{G(x_1, \ldots, x_m)}{G(a_1 x_1, \ldots, a_m x_m)} \right)^{q_n},
\]
where \( 0 < c_1 < T_n < c_2 \).

Assume that \( (a_1, \ldots, a_m) \neq (1, \ldots, 1) \). By Lemma 3.2, we can find positive rational vector \( (x_1, \ldots, x_n) \) such that \( G(x_1, \ldots, x_m)/G(a_1 x_1, \ldots, a_m x_m) \neq 1 \), and so that (3.8) contradicts (3.7). Thus \( p_j = q_j \) for all \( j \) and \( \rho = \tau \). \( \square \)

The combination of Lemma 3.1 and Lemma 3.3 immediately yields Theorem 1.3.

4. TWO-BRANCH DUST-LIKE CANTOR SETS

In this section we focus on two-branch dust-like self-similar sets, i.e. dust-like self-similar sets generated by two contractions \( D(\rho_1, \rho_2) \) and prove Theorem 1.4. We will first need to introduce some results on polynomials with integer coefficients.

Consider the polynomial \( f(x) = x^n + x^m - 1 \) where \( n > m > 0 \). It is easy to show that there exists a unique \( x_0 \in (0, 1) \) such that \( f(x_0) = 0 \). We denote this root \( x_0 \) by \( r_{n,m} \).

**Proposition 4.1** ([9], Theorem 3). Let \( n \geq 2m > 0 \). Write \( n = n_1 \ell, \ m = m_1 \ell \) where \( \ell = \gcd(n, m) \). Then the polynomial
\[ g(x) = x^n + \varepsilon x^m + \delta, \quad \varepsilon, \delta \in \{1, -1\} \]
is irreducible unless \( n_1 + m_1 \equiv 0 \mod 3 \) and one of the following three conditions holds:

1. \( n_1, m_1 \) are both odd and \( \varepsilon = 1 \).
2. \( n_1 \) is even and \( \delta = 1 \).
3. \( m_1 \) is even and \( \varepsilon = \delta \).

In any of these exceptional cases, \( g(x) \) is the product of the polynomial
\[ x^{2\ell} + \varepsilon^{m_1} \delta^{n_1} x^\ell + 1 \]
and a second irreducible polynomial.
To prove Theorem 1.4 we will need to examine the conditions for $r_{n,m} = r_{q,p}$.
Clearly if one of $n, m$ is equal to one of $p, q$ then the other must equal as well.
Without loss of generality we assume that $n > q$. In this case we must have $n > q > p > m$.

**Lemma 4.2.** Let $n > q > p > m$ be positive integers with $\gcd(n, m, q, p) = 1$.
Then $r_{n,m} = r_{q,p}$ if and only if $(n, m, q, p) = (5, 1, 3, 2)$.

**Proof.** It is easy to check that if $(n, m, q, p) = (5, 1, 3, 2)$ then $r_{n,m} = r_{q,p}$ because
$$x^2 + x - 1 = (x^2 + x - 1)(x^2 - x + 1).$$

The other direction is more involved. We consider several cases and apply Proposition 4.1.
Let $f(x) = x^n + x^m - 1$ and $g(x) = x^q + x^p - 1$. Assume that $r_{n,m} = r_{q,p}$.
Then $f(x)$ must be reducible. By Proposition 4.1, if $n \geq 2m$ then
$$f(x) = (x^{2\ell} \pm x^\ell + 1)h_1(x),$$
where $h_1(x)$ is irreducible and $\ell = \gcd(n,m)$. If $n < 2m$ we may consider the polynomial
$$-x^n f(x^{-1}) = x^n - x^{n-m} - 1,$$
which is reducible and thus has the form $-x^n f(x^{-1}) = (x^{2\ell} \pm x^\ell + 1)h_2(x)$ so that
$$f(x^{-1}) = (1 \pm x^{-\ell} + x^{-2\ell})(-x^{-(n-2\ell)}h_2(x)).$$
In both cases we obtain
$$f(x) = (x^{2\ell} \pm x^\ell + 1)h(x),$$
where $h(x)$ is irreducible by Proposition 4.1. Since all roots of $x^{2\ell} \pm x^\ell + 1$ are irreducible
on the unit circle, we know that $h(r_{n,m}) = 0$. It follows that $h(x) | g(x)$. We now consider two cases.

**Case 1.** Assume that $g(x)$ is irreducible so that $h(x) = g(x)$. We have
$$x^n + x^m - 1 = (x^{2\ell} \pm x^\ell + 1)(x^q + x^p - 1)$$
$$= x^{p+2\ell} + x^{p+\ell} - x^{2\ell} + \varepsilon x^q + \varepsilon x^{p+\ell} - \varepsilon x^\ell + x^q + x^p - 1,$$
where $\varepsilon \in \{1, -1\}$. It follows that $n = q + 2\ell$ and the middle seven terms on the right hand side must combine to become $x^m$.
Suppose $\varepsilon = 1$ we note that if we set $x = 1$ then the two sides are not equal, which is a contradiction. Hence we must have $\varepsilon = -1$. This yields
$$x^{p+2\ell} - x^{2\ell} - x^{q+\ell} - x^{p+\ell} + x^q + x^p = x^m.$$
But $m < p < q$. It follows that $m = \ell$, $p = 2\ell$, $q = p + \ell = 3\ell$ and $p + 2\ell = q + \ell$. Now $n = q + 2\ell = 5\ell$. Since $\gcd(n,m,q,p) = 1$ we have $\ell = 1$ and $(n, m, q, p) = (5, 1, 3, 2)$.

**Case 2.** Assume that $g(x)$ is reducible. Then as before $g(x) = (x^{2\ell} \pm x^\ell + 1)k(x)$,
where $\gcd(q, p) = e$, $k(x)$ is irreducible and $e \in \{1, -1\}$. Since $x^{2\ell} \pm x^\ell + 1$ has no root in $(0, 1)$ so again $k(r_{q,p}) = 0$. It follows from the fact that both $h(x)$ and $k(x)$ are irreducible that $h(x) = k(x)$. Thus
$$(x^{2\ell} + \delta x^\ell + 1)(x^n + x^m - 1) = (x^{2\ell} \pm x^\ell + 1)(x^q + x^p - 1).$$
Plug in $x = 1$ we see easily that $\varepsilon = \delta$. From $n + 2\ell = q + 2\ell$ we know that $e \leq \ell$.
In particular since $\ell = \gcd(n,m)$ we also have $e < m$. But this means the term $-\delta x^\ell$ on the left hand side cannot be cancelled out by any other term on the left hand side. Nor can it be cancelled out by any term on the right hand side because $q > p > m \geq \ell > e$. This is impossible. \hfill□

We can now complete the proof of Theorem 1.4.

**Proof of Theorem 1.4.** First we prove the if part. It suffices to show that $D(\lambda^5, \lambda) \sim D(\lambda^3, \lambda^2)$. Note that iterating the $\lambda$ term in $(\lambda^5, \lambda)$ leads to contraction
Assume that the condition (2) in Theorem 1.4 must hold. Let \( c = \text{rank}(\rho_1, \rho_2) \). If \( c = 2 \) then \((\tau_1, \tau_2)\) must be a permutation of \((\rho_1, \rho_2)\) by Theorem 1.3. This yields \((\rho_1, \rho_2) = (\tau_1, \tau_2)\), a contradiction. So we must have \( \text{rank}(\rho_1, \rho_2, \tau_1, \tau_2) = 1 \) and thus there exists a \( \lambda \in (0, 1) \) such that

\[
\rho_1 = \lambda^n, \quad \rho_2 = \lambda^m, \quad \tau_1 = \lambda^q, \quad \tau_2 = \lambda^p
\]

for some positive integers \( n, m, q, p \) with \( \gcd(n, m, q, p) = 1 \).

Let \( s \) be the common Hausdorff dimension of \( E \) and \( F \), then \( x^n + x^m = 1 \) and \( x^q + x^p = 1 \) for \( x = \lambda^s \). Thus, from assumptions \( \rho_1 \leq \rho_2, \tau_1 \leq \tau_2, \rho_1 \leq \tau_1 \) and \( (\rho_1, \rho_2) \neq (\tau_1, \tau_2) \), we must have \( n > p > q > m \). Note that if \( p = q \) then the roots of \( x^n + x^m - 1 = 0 \) are all algebraic integers while \( x = \sqrt[6]{1/2} \) is not an algebraic integer, which is a contradiction. Thus we have \( n > q > p > m \). It follows from Lemma 4.2 that \((n, m, q, p) = (5, 1, 3, 2)\) so that condition (2) holds. This proves the theorem.

5. Theorem 1.5 and Some Other Results

In the study of self-similar sets it is useful to consider the symbolic spaces. For any \( m \geq 1 \) let \( \Sigma_m \) denote the set of all words \( w = i_1i_2i_3\cdots \) with infinite length where each \( i_j \in \{1, 2, \ldots, m\} \). For such a \( w \in \Sigma_m \) we use the notation \( w(k) = i_k \) and \( |w|_k = i_{k+1} \ldots i_k \). For any \( \rho = (\rho_1, \rho_2, \ldots, \rho_m), \ 0 < \rho_j < 1 \), we can define a metric \( d_\rho \) on \( \Sigma_m \) as follows: Let \( z, w \in \Sigma_m \). If \( z(1) \neq w(1) \) then set \( d_\rho(z, w) = 1 \); otherwise set \( d_\rho(z, w) = \rho_k \), where \( |z|_k = |w|_k \) but \( z(k + 1) \neq w(k + 1) \), and \( \rho_k := \prod_{j=1}^k \rho_{z(j)} \). It is well known that \( d_\rho \) is indeed a metric on \( \Sigma_m \). We shall denote the metric space \( \Sigma_m \) associate with this metric by \((\Sigma_m, d_\rho)\).

**Lemma 5.1.** Let \( \rho = (\rho_1, \ldots, \rho_m) \) be a contraction vector and \( E \in D(\rho) \). Then there exists a bi-Lipschitz map from \((\Sigma_m, d_\rho)\) to \( E \).

**Proof.** Assume that \( E \) is the attractor of the IFS \( \{\phi_j\}_{j=1}^m \) where the contraction ratio of \( \phi_j \) is \( \rho_j \). Fix some \( a \in E \). Since the IFS satisfies the strong open set condition each \( x \in E \) has a unique representation \( x = \phi_w(a) \) where \( w = i_1i_2\cdots \in \Sigma_m \), using the standard notation \( \phi_w(a) := \lim_{k \to \infty} \phi_{i_1} \circ \phi_{i_2} \circ \cdots \circ \phi_{i_k}(a) \). Let \( C_1 \) denote the smallest distances among the sets \( \{\phi_j(E)\}_{j=1}^m \). Let \( C_2 \) denote the diameter of \( E \).

Now define \( f : (\Sigma_m, d_\rho) \rightarrow E \) by \( f(w) = \phi_w(a) \). Note that \( E \) is dust-like so that

\[
C_1 d_\rho(w, z) \leq |\phi_w(a) - \phi_z(a)| \leq C_2 d_\rho(w, z).
\]

It follows that \( f \) is a bi-Lipschitz map from \((\Sigma_m, d_\rho)\) to \( E \). \( \square \)

**Theorem 5.2.** Assume that \( D(\rho_1, \ldots, \rho_m) \) and \( D(\tau_1, \ldots, \tau_n) \) are Lipschitz equivalent. Let \( s = \dim_H D(\rho_1, \ldots, \rho_m) \). Then for any \( r > s \), \( D(\rho_1^r, \ldots, \rho_m^r) \) and \( D(\tau_1^r, \ldots, \tau_n^r) \) are also Lipschitz equivalent.

**Proof.** Let \( \rho^r = (\rho_1^r, \ldots, \rho_m^r) \) and \( \tau^r = (\tau_1^r, \ldots, \tau_n^r) \). By Lemma 5.1 it suffices to establish the Lipschitz equivalence of \((\Sigma_m, d_\rho^r)\) and \((\Sigma_n, d_{\tau^r})\). Since \( D(\rho) \) is
Lipschitz equivalent to $\mathcal{D}(\tau)$, there is a bi-Lipschitz map $f : (\Sigma_m, d_\rho) \rightarrow (\Sigma_n, d_\tau)$, with
\begin{equation}
C' d_\rho(z, w) \leq d_\tau(f(z), f(w)) \leq C d_\rho(z, w)
\end{equation}
for all $z, w \in (\Sigma_m, d_\rho)$, where $C, C' > 0$.

Remark: Note that it is possible that $\rho \sim \tau$ but one is not derived from another. One such example is $\rho = (\rho^3, \rho)$ and $\tau = (\rho^3, \rho^2)$. Observe that $(\rho^3, \rho^3, \rho^2)$ is derived both from $\rho$ and $\tau$. Thus $\rho \sim \tau$. However neither is derived from the other. In fact, it is possible to show that there exists no dust-like self-similar set that is the attractor of both $\Phi$ with contraction ratios $\rho$ and $\Psi$ with contraction ratios $\tau$. 

We now consider another kind of Lipschitz equivalence. Let $\rho = (\rho_1, \ldots, \rho_m)$ and $\tau = (\tau_1, \ldots, \tau_n)$ be two contraction vector. It is clear that if $(\tau_1, \ldots, \tau_m)$ is a permutation of $(\rho_1, \ldots, \rho_m)$ then $\mathcal{D}(\rho) = \mathcal{D}(\tau)$. So we may without of loss generality from now on assume that all contraction ratios $\rho = (\rho_1, \ldots, \rho_m)$ are in the standard form in the sense that $0 < \rho_1 \leq \rho_2 \leq \cdots \leq \rho_m < 1$. Let $\Phi := \{\phi_j\}_{j=1}^m$ be an IFS with contraction ratios $\rho = (\rho_j)$ that satisfies the SSC. The attractor $E$ of $\Phi$ is the unique compact set satisfying $E = \bigcup_{j=1}^m \phi_j(E)$. With the SSC all $\{\phi_j(E)\}_{j=1}^m$ are disjoint. We say that an IFS $\Psi = \{\psi_i\}_{i=n}^1$ is derived from $\Phi$ if $\Psi(E) = E$, all $\{\psi_i(E)\}$ are disjoint, and each $\psi_i$ has the form
$$\psi_i(x) = \phi_{j_1} \circ \phi_{j_2} \circ \cdots \circ \phi_{j_k}(x)$$
for some $1 \leq j_1, j_2, \ldots, j_k \leq m$.

Definition 5.3. Let $\rho$ and $\tau$ be two contraction vector. We say $\tau$ is derived from $\rho$ if there is an IFS $\Phi = \{\phi_j\}_{j=1}^m$ with contraction vector $\rho$ satisfying the SSC and another IFS $\Psi = \{\psi_i\}_{i=n}^1$ with contraction vector $\tau$ such that $\Psi$ is derived from $\Phi$. We say $\rho$ and $\tau$ are equivalent, and denoted it by $\rho \sim \tau$, if there exists a sequence $\rho = \rho_1, \rho_2, \ldots, \rho_N = \tau$ such that $\rho_{j+1}$ is derived from $\rho_j$ or vice versa for $1 \leq j < N$.

Lemma 5.4. Assume that $\rho$ is equivalent to $\tau$. Then $\mathcal{D}(\rho) \sim \mathcal{D}(\tau)$.

Proof. By definition there exists a sequence $\rho = \rho_1, \rho_2, \ldots, \rho_N = \tau$ such that $\rho_{j+1}$ is derived from $\rho_j$ or vice versa for any $1 \leq j < N$. We only need to prove that $\mathcal{D}(\rho_j) \sim \mathcal{D}(\rho_{j+1})$. To this end we may assume without loss of generality that $\tau$ is derived from $\rho$, and prove that $\mathcal{D}(\rho) \sim \mathcal{D}(\tau)$. But by definition there exist IFSs $\Phi$ and $\Psi$ with contraction ratios $\rho$ and $\tau$, respectively, satisfying the SSC such that $\Psi$ is derived from $\Phi$. Thus they have the same attractor, and hence $\mathcal{D}(\rho) \sim \mathcal{D}(\tau)$. 

Remark: Note that it is possible that $\rho \sim \tau$ but one is not derived from another. One such example is $\rho = (\rho^3, \rho)$ and $\tau = (\rho^3, \rho^2)$. Observe that $(\rho^3, \rho^3, \rho^2)$ is derived both from $\rho$ and $\tau$. Thus $\rho \sim \tau$. However neither is derived from the other. In fact, it is possible to show that there exists no dust-like self-similar set that is the attractor of both $\Phi$ with contraction ratios $\rho$ and $\Psi$ with contraction ratios $\tau$. 

Proof of Theorem 1.5. Assume that $\mathcal{D}(\rho) \sim \mathcal{D}(\tau)$. We prove (1) and (2). The condition (1) is obvious because the two classes of sets have the same Hausdorff dimension, which is $\log m/\log(\rho^{-1})$. We now prove (2). By Theorem 1.2 there exists some $q \in \mathbb{Z}^+$ such that

$$\sgp(\tau_1^q, \ldots, \tau_m^q) \subset \sgp(\rho_1, \ldots, \rho_m) = \{1, \rho, \rho^2, \ldots\}.$$  

Thus each $\tau_j^q = \rho^{p_j}$ for some $p_j \in \mathbb{N}$, and hence $\tau_j = \rho^{p_j/q}$. We may without loss of generality assume that $q$ is coprime with $\gcd(p_1, \ldots, p_n)$. 

Now $mp^q = 1$ and $p^q = 1/m$ so that $\mathbb{Q}(\tau_1^q, \ldots, \tau_m^q) = \mathbb{Q}(\rho^q) = \mathbb{Q}$. It follows that

$$\log(\tau_j^q) \in \mathbb{Q}.$$  

Thus letting $r_j = \rho^{p_j/q}$ so that $\log r_j/\log \rho \in 1/\mathbb{Z}$.

Conversely, assume that conditions (1) and (2) hold. Define $\lambda = \rho^{1/q}$. Given $j = 1, \ldots, n$, we know from $\log r_j/\log \rho \in \frac{1}{q}\mathbb{Z}^+$ that $\log(r_j/\log \lambda) \in \mathbb{Z}^+$, and hence $\tau_j = \lambda^{p_j}$ for some $p_j \in \mathbb{Z}^+$. We prove $\mathcal{D}(\rho) \sim \mathcal{D}(\tau)$ by showing that $\rho \sim \tau$.

Define $k = m^{1/q}$. Write $\Lambda = (\lambda, \ldots, \lambda) \in \mathbb{R}^k$. Note that $kk^\lambda = 1$ because $(kk^\lambda)^q = m^{p^q} = 1$. With $0 < s < 1$ we know that there exists an IFS $\Phi = \{\phi_j\}_{j=1}^k$ with the SSC and contraction vector $\lambda$. We introduce the following notation. Let $r$ be any given positive integer. For any $j = j_1, j_2, \ldots, j_r \in \{1, 2, \ldots, k\}^r$ we shall use $\phi_j$ to denote the map $\phi_j = \phi_j \circ \phi_{j_2} \circ \cdots \circ \phi_{j_r}$. Denote by $\Phi^r$ the IFS $\Phi^r = \{\phi_j : j \in \{1, 2, \ldots, k\}^r\}$. Clearly $\Phi^r$ is an iterate of $\Phi$, and it has contraction vector $(\lambda^{r_1}, \lambda^{r_2}, \ldots, \lambda^{r_k}) \in \mathbb{R}^k$. Thus letting $r = q$ we see that $\rho$ is derived from $\Lambda$ and hence $\lambda \sim \rho$. We prove that $\lambda \sim \tau$ also.

Without loss of generality we assume that $p_1 \leq p_2 \leq \cdots \leq p_n$. We show that there exists an iterate $\Psi$ of $\Phi$ such that the contraction ratios of $\Psi$ are given by $\tau$. This can be proved by selectively iterating the maps in $\Phi$. First set

$$\Phi_1 := \Phi^{p_1} = \{\phi_j : j \in \{1, 2, \ldots, k\}^{p_1}\}.$$  

Note that all $\phi_j$ in $\Phi_1$ has contraction ratio $\lambda^{p_1}$. Next we leave one of the maps in $\Phi_1$, say, $\phi_{j_1}$, intact and iterate the rest of maps as follows: We replace each $\phi_k$ where $k \neq j_1$ by the maps $\phi_k \circ \phi_{j_1}$, $i \in \{1, \ldots, k\}\setminus\{p_1\}$. (Here if $p_2 = p_1$ we do nothing.) This leads to another IFS $\Phi_2$ that is an iterate of $\Phi_1$, and it has the property that with the exception of the one map $\phi_{j_1}$ all other maps in it have contraction ration $\lambda^{p_2}$. We select one of them and label it $\phi_{j_2}$.

This process is now continued further. For each $\phi_j$ in $\Phi_2$ that is not $\phi_{j_1}$ and $\phi_{j_2}$, we iterate it by replacing $\phi_j$ with the maps $\phi_k \circ \phi_{j_1}$, $i \in \{1, \ldots, k\}^{p_3-p_2}$. (Again if $p_3 = p_2$ we do nothing.) These iterations lead to the IFS $\Phi_3$, where with the exception of the maps $\phi_{j_1}, \phi_{j_2}$ all other maps have contraction ratios $\lambda^{p_3}$. We select one of them and label it $\phi_{j_3}$.

Continue this process we eventually obtain an IFS $\Phi_L = \{\phi_{j_1}, \phi_{j_2}, \ldots, \phi_{j_L}\}$. Finally, we show that $L = n$. If $L < n$ then the contraction ratios of $\Phi_L$ are $(\tau_j) \in \mathbb{R}^L$. But the attractor of $\Phi_L$ is the same as the attractor of $\Phi$, which has Hausdorff dimension $s$. Thus $\sum_{j=1}^L \tau_j^s = 1$, but this contradicts $\sum_{j=1}^L \tau_j^p = 1$. Thus $L \geq n$. By the same argument we cannot have $L > n$. Hence $L = n$. It follows that the contraction ratios of $\Phi_L$ are given by $\tau$. This $\tau$ is derived from $\lambda$ and hence $\tau \sim \lambda$. It follows that $\rho \sim \tau$. The theorem is thus proved. \qed
Acknowledgements. We are grateful to Martin Kassabov and Ravi Ramakrishna for discussions in connection with the material in section 4, and to Andrzej Schinzel for pointing out the reference [9].

Appendix A. The proof of Lemma 2.7

Proof. Since $F$ is dust-like, $F$ satisfies the open set condition, i.e., there exists an open set $V$, such that $V \supset \bigcup_{n=1}^\infty \psi_1(V)$ and $\psi_i(V) \cap \psi_j(V) = \emptyset$ for distinct $i, j$. It is clear that there exists a ball $B$ in $V$. Now, given a nonempty set $A \subset \mathbb{R}^d$. Define

$$\mathcal{I} = \{ i : F_i \cap A \neq \emptyset \text{ and } c_1 \text{diam } A \leq \text{diam } F_i \leq c_2 \text{diam } A \}.$$ 

Take any $J \subset \mathcal{I}$ such that $F_i \cap F_j = \emptyset$ for any distinct $i, j \in J$. It suffices to prove that card $(J)$ is bounded.

For each $i \in J$, we define $\delta_i = \text{diam } F_i \cdot \frac{\text{diam } V}{\text{diam } F_i}$ and $N_{\delta_i}(A) = \{ y : d(x, y) < \delta_i \text{ for some } x \in A \}$. Then $N_{\delta_i}(A) \supset \psi_i(V) \supset \psi_i(B)$. Let $\delta = \sup \{ \delta_i : i \in J \}$, then $\delta \leq \text{diam } A \cdot \frac{\text{diam } V}{\text{diam } F_i}$ and

$$N_{\delta}(A) \supset \cup_{i \in J} \psi_i(B).$$

We will show that the union in the right hand side is disjoint. Otherwise, assume that $\psi_i(B) \cap \psi_j(B) \neq \emptyset$ for distinct $i, j \in J$. Then $\psi_i(V) \cap \psi_j(V) \neq \emptyset$. By the open set condition, we must have $\psi_i(V) \subset \psi_j(V)$ or $\psi_j(V) \subset \psi_i(V)$. It follows that $F_i \subset F_j$ or $F_j \subset F_i$, which contradicts the mutual disjointness of $F_i$.

Notice that $\psi_i(B)$ is a ball with diameter $\frac{\text{diam } F_i \cdot \text{diam } B}{\text{diam } F_i} \leq c_1 \text{ diam } A \cdot \frac{\text{diam } B}{\text{diam } F_i} =: c_1^* \text{ diam } A$, and $N_{\delta}(A)$ is contained in a ball with diameter $2(|A| + \delta) \leq 2 \text{ diam } A \cdot (1 + \frac{\text{diam } V}{\text{diam } F_i}) =: c_2^* \text{ diam } A$. Thus $N_{\delta}(A)$ can contain at most $c_3 := c_2^* c_1^* \text{diam } A$ mutually disjoint $\psi_i(B)$ so that card $(J) \leq c_3$.

Notice that $c_3 = (c_2^* c_1^*)^d$, where $c_1^*$ and $c_2^*$ are two positive constants only dependent on $c_1, c_2$ and the IFS $\{ \psi_i \}$. This completes the proof of the lemma. □
