SINGULARITY ANALYSIS FOR INTEGRABLE SYSTEMS
BY THEIR MIRRORS

JISHAN HU * AND MIN YAN †

Abstract. We use the Lorenz system, the Rikitake model and the nonlinear Schrödinger
equation to demonstrate that for completely integrable systems, there exist what we
call the regular mirror systems near movable singularities. The method for finding
the mirror systems is very similar to the original WTC version of the Painlevé test
[8]. It tests the complete integrability and gives a systematic and conceptual proof
that the formal Laurent series generated by the Painlevé test are convergent.

AMS classification scheme numbers: 35Q51, 58F07

of the equation

\[ u'' = 6u^2 + x, \quad (1.1) \]

he introduced two new dependent variables \( \theta \) and \( \xi \) by

\[ u = \theta^{-2}, \quad \theta' = 1 + \frac{1}{4} x \theta^4 + \frac{1}{4} \theta^5 - \frac{1}{2} \theta^6 \xi, \]

†Address: Department of Mathematics, The Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong. Email: mamyan@uxmail.ust.hk. Fax number: (852)2358-1643.
and converted the equation into the following regular system

\[
\begin{align*}
\frac{d\theta}{dx} &= 1 + \frac{1}{4} x \theta^4 + \frac{1}{4} \theta^5 - \frac{1}{2} \theta^6 \xi, \\
\frac{d\xi}{dx} &= \frac{1}{8} x^2 \theta + \frac{3}{8} x \theta^2 + \theta^3 \left(\frac{1}{4} - x \xi\right) - \frac{5}{4} \theta^4 \xi - \frac{3}{2} \theta^5 \xi^2.
\end{align*}
\]

This differential system (which we called the mirror system in [3] [4]) determines the behaviors of solutions near their algebraic movable singularities. The regularity of the system makes it possible to apply the Cauchy-Kowalevski theorem. This implies that the solutions of (1.1) must be meromorphic near algebraic movable singularities.

Our recent work [3] has demonstrated that, for single high order equations, what Painlevé did a century ago is a general property. In fact, we will argue in [4] that the existence of regular mirror systems is equivalent to the Painlevé test [1] [8], which has been the most effective algorithm for detecting complete integrability. Moreover, we can use the mirror system to show that the formal Laurent series solutions obtained from the Painlevé test must be convergent, and thereby justify the Painlevé test.

The first purpose of this paper is to demonstrate how to apply the similar idea to systems of differential equations. Secondly, we have gained much insight in our algorithm since we finished [3], and we would like to take the opportunity to present our algorithm in a more understandable way (and to incorporate the necessary changes needed for systems). We will work out the details for the examples of the Lorenz system, the Rikitake model, and the nonlinear Schrödinger equation. The treatment of the Lorenz system is the most standard. The Rikitake model has a double root as resonance. And the nonlinear Schrödinger equation is a PDE, with one resonance parameter appearing as leading behavior.

Our construction of the mirror system is done under the best scenario assumption. As we will argue in [4], successfully carrying out our construction is in fact equivalent to passing the Painlevé test (meaning there is enough number of non-negative
Mirror systems

It is quite possible that we can still construct some sort of partial mirror system in cases such as insufficient number of resonances, negative resonances, or fractional resonances. We will try to explore these in future research.

2. Algorithm for Mirror Systems. Our algorithm for finding the mirror systems for differential systems is based on a computation similar to the original version of Weiss, Tabor, and Carnevale’s Painlevé test for PDEs [8]. We outline the steps as follows, using a first order ODE system in dependent variables $X$, $Y$, and $Z$ as example.

Step 1: Find the dominant behavior in the neighborhood of the movable singularity.

Step 2: Introduce indicial normalization by writing one dependent variable in the form $\theta^{-k}$, where $k$ is the leading exponent of the dependent variable.

Suppose our ODE system has the following dominant behavior

$$X = X_0(t - t_0)^{-k}, \quad Y = Y_0(t - t_0)^{-l}, \quad Z = Z_0(t - t_0)^{-m}$$

near movable singularities (only one of $k$, $l$, and $m$ needs to be positive). Then we may choose a positive leading exponent, say $k$, and introduce indicial normalization $X = \theta^{-k}$.

Step 3: Find formal Laurent series of $\theta'$ and the other dependent variables in powers of $\theta$.

For our ODE system, we are looking for the following formal Laurent $\theta$-series

$$\begin{align*}
\theta' &= a_0 + a_1 \theta + a_2 \theta^2 + \cdots, \\
Y &= \theta^{-l}(b_0 + b_1 \theta + b_2 \theta^2 + \cdots), \\
Z &= \theta^{-m}(c_0 + c_1 \theta + c_2 \theta^2 + \cdots),
\end{align*}$$

(2.1)

where $a_*$, $b_*$, and $c_*$ functions of $t$ (but not $t_0$). The way to find these is similar to the Painlevé test. The leading coefficients $a_0$, $b_0$, and $c_0$ can be found from the dominant
balance equations. The later coefficients are computed from a linear recursive relation obtained by substituting the series (2.1) into the system.

There is one important difference between our algorithm and the Painlevé test: The function \( \phi \) used in [8] to define the singularity manifold depends only on the singularity, and is independent of the resonance parameters. In our algorithm, the function \( \theta \) is “equivalent” to the solution, and has the resonance parameters implicitly built in. This is reflected in that, in substituting (2.1) into the original system, we need to use

\[
X' = -k\theta^{-k-1}\theta' = -k\theta^{-k-1}(a_0 + a_1\theta + a_2\theta^2 + \cdots),
\]

and

\[
Y' = \theta^{-l}(b'_0 + b'_1\theta + b'_2\theta^2 + \cdots)
\]

\[
+ \theta^{-l-1}((-l)b_0 + (-l + 1)b_1\theta + (-l + 2)b_2\theta^2 + \cdots)(a_0 + a_1\theta + a_2\theta + \cdots),
\]

and similarly for \( Z' \).

For autonomous systems, the coefficients \( a_\ast, b_\ast, \) and \( c_\ast \) are constants. This makes the computation a little easier.

For our ODE system, the determinant of the coefficient matrix in the recursive relation is a polynomial of degree 3. It has the same roots (resonances) as the determinant in the Painlevé test. The compatibility in our sense is equivalent to the compatibility in the Painlevé test. If \( j \) is the largest resonance, then we may stop the computation until \( a_j, b_j, \) and \( c_j \) are found.

Step 4: Truncate the Laurent \( \theta \)-series of the dependent variables at the resonances one after another by introducing new variables.

For the third order system, we expect to get two resonance parameters \( r_1 \) and \( r_2 \).
at resonances $j_1 \leq j_2$. Suppose we have

$$Y = \theta^{-1}(b_0 + b_1 \theta + b_2 \theta^2 + \cdots + (p_1 \tau_1 + q_1)\theta^{j_1} + \cdots),$$

with $p_1 \neq 0$ (if this does not happen for $Y$, then this happens for $Z$). Then we introduce $\xi$ by truncating $Y$ at $r_1$

$$Y = \theta^{-1}(b_0 + b_1 \theta + b_2 \theta^2 + \cdots + \xi \theta^{j_1}). \quad (2.2)$$

Moreover, we may convert

$$\xi = p_1 \tau_1 + q_1 + b_{j_1+1} \theta + b_{j_1+2} \theta^2 + \cdots,$$

and get

$$r_1 = p_1^{-1}(\xi - q_1) + \beta_1 \theta + \beta_2 \theta^2 + \cdots.$$

Substituting this into the $\theta$-series of $Z$, we get

$$Z = \theta^{-m}(c_0 + c_1 \theta + c_2 \theta^2 + \cdots + (p_2 \tau_2 + q_2)\theta^{j_2} + \cdots),$$

where $p_2$ is necessarily nonzero and the coefficients only involve $t$, $\xi$, and $r_2$ (not involving $t_0$ and $r_1$). Then we introduce $\eta$ by truncating $Z$ at $r_2$

$$Z = \theta^{-m}(c_0 + c_1 \theta + c_2 \theta^2 + \cdots + \eta \theta^{j_2}). \quad (2.3)$$

**Step 5:** Convert the original differential system into a differential system (the mirror system) about new variables.

The formulas $X = \theta^{-k}$, (2.2), and (2.3) is a transformation between $(X, Y, Z)$ and $(\theta, \xi, \eta)$. If the system for $(X, Y, Z)$ passes the Painlevé test, then the mirror system for $(\theta, \xi, \eta)$ should be regular [4].

This completes the description of the algorithm.
The method also applies to higher order case. We only need to use

\[ X'' = (-k)(-k - 1)\theta^{-k-2}\theta^2 - k\theta^{k-1}\theta'' \]

\[ = (-k)(-k - 1)\theta^{-k-2}(a_0 + a_1\theta + a_2\theta^2 + \cdots)^2 \]

\[ -k\theta^{k-1}(a_0' + a_1'\theta + a_2'\theta^2 + \cdots) \]

\[ -k\theta^{k-1}(a_1 + 2a_2\theta + \cdots)(a_0 + a_1\theta + a_2\theta^2 + \cdots), \]

and similar formulae for \( Y'' \), \( Z'' \) and higher derivatives.

The method also applies to PDE systems. The only difference is that the coefficients in the \( \theta \)-series involve more variables, and we need to use formulae such as

\[ \partial_y Y = \theta^{-1}(\partial_y b_0 + (\partial_y b_1)\theta + (\partial_y b_2)\theta^2 + \cdots) \]

\[ + \theta^{-1-1}((-l)b_0 + (-l + 1)b_1\theta + (-l + 2)b_2\theta^2 + \cdots)(\partial_y \theta). \]

In particular, the coefficients of the \( \theta \)-series may involve \( \partial_y \theta, \partial_y^2 \theta, \cdots \).

3. Examples of Mirror Systems. The Painlevé test has been used to uncover integrable cases of many systems of physical interest. For example, Segur found four integrable cases for the Lorenz system [7]. More examples can be found in [2] [6]. In this section, we demonstrate our algorithm by working out some classical examples.

3.1. The Lorenz system. The Lorenz system is an autonomous differential system:

\[
\begin{align*}
X' &= \sigma(Y - X), \\
Y' &= -XZ + RX - Y, \\
Z' &= XY - BZ,
\end{align*}
\]  

(3.1)

where \( \sigma, R, \) and \( B \) are constants. In general, this system is not integrable and is well known for the chaotic behavior of its solutions. The Painlevé test tells us four completely integrable cases for the Lorenz system:
1. $\sigma = 0$;
2. $\sigma = 1/2, B = 1, R = 0$;
3. $\sigma = 1, B = 2, R = 1/9$;
4. $\sigma = 1/3, B = 0, R$ arbitrary.

If $\sigma = 0$, then $X$ is a constant and the system is linear. Therefore we will not investigate the case anymore. The three other cases were found by the Painlevé test.

In what follows, we try to carry out our algorithm for the Lorenz system. We will see that we are successful in exactly these three cases.

By dominant balance we find the leading behavior

$$X = X_0(t - t_0)^{-1}, \quad Y = Y_0(t - t_0)^{-2}, \quad Z = Z_0(t - t_0)^{-2},$$

near a movable singularity $t = t_0$. This suggests us to introduce the indicial normalization $X = \theta^{-1}$ and try to compute the formal $\theta$-series (2.1), with $l = m = 2$ and $a_*, b_*, c_*$ constants (because the system is autonomous).

Substituting (2.1) into the Lorenz system, we get the equations for the leading coefficients

$$a_0 = -\sigma b_0, \quad -2a_0b_0 = -c_0, \quad -2a_0c_0 = b_0; \quad (3.2)$$

and the recursive relation for the higher order coefficients

$$\begin{cases}
    a_n + \sigma b_n &= \delta_{1,n}\sigma, \\
    -2b_0a_n + (n-2)a_0b_n + c_n &= \delta_{2,n}R - b_{n-1} - \sum_{j=1}^{n-1} (j-2)a_{n-j}b_j, \\
    -2c_0a_n - b_n + (n-2)a_0c_n &= -Bc_{n-1} - \sum_{j=1}^{n-1} (j-2)a_{n-j}c_j.
\end{cases} \quad (3.3)$$

By solving (3.2), we find two possible branches of leading behaviors

$$a_0 = \pm \frac{i}{2}, \quad b_0 = \mp \frac{i}{2\sigma}, \quad c_0 = \frac{1}{2\sigma}. $$

Substituting these into the coefficient matrix on the left of (3.3), we see that the determinant of the coefficient matrix is $-\frac{1}{4}(n-2)(n-4)$. Therefore there are two
resonances \( j = 2, 4 \), and we need to find the compatibility condition for each resonance.

We will carry this out only for the branch \( a_0 = i/2 \). The discussion for the other branch is similar.

From the recursive relation (3.3), we find

\[
\begin{align*}
a_1 &= \frac{1}{3} - \sigma + \frac{2}{3} B, \\
b_1 &= 2 - \frac{1}{3\sigma} - \frac{2}{3\sigma} B, \\
c_1 &= 2i - \frac{i}{\sigma} B.
\end{align*}
\]

Then for \( n = 2 \), the recursive relation becomes

\[
\begin{align*}
a_2 + \sigma b_2 &= 0, \\
\frac{i}{\sigma} a_2 + c_2 &= -1 - 2\sigma + \frac{2}{9\sigma} + 2B + \frac{2}{9\sigma} B - \frac{4}{9\sigma} B^2 + R, \\
-\frac{1}{\sigma} a_2 - b_2 &= 2i - 2i\sigma + i\frac{3}{\sigma} B - i\frac{3}{\sigma} B + i\frac{3}{\sigma} B^2.
\end{align*}
\]

(3.4)

The system is consistent if and only if

\[
B^2 + B (-1 + \sigma) + 2 (1 - 3\sigma) \sigma = 0.
\]

This means that we need to consider two possibilities

\[
B = 2\sigma, \quad \text{or} \quad B = 1 - 3\sigma.
\]

**Case 1: \( B = 2\sigma \).**

In this case, we solve (3.4) and get

\[
\begin{align*}
a_2 &= -\sigma r_1, \\
b_2 &= r_1, \\
c_2 &= i r_1 - \frac{5}{9} + \frac{2}{9\sigma} + \frac{2\sigma}{9} + R,
\end{align*}
\]

where \( r_1 \) is the first resonance parameter. Then from the recursive relation, we further have

\[
\begin{align*}
a_3 &= \frac{4i}{3} \sigma r_1 - \frac{20i}{3} \sigma^2 r_1 - \frac{16}{9} \sigma + \frac{40}{9} \sigma^2 - \frac{16}{9} \sigma^3 - 8R\sigma^2, \\
b_3 &= \frac{4i}{3} r_1 + \frac{20i}{3} \sigma r_1 + \frac{16}{9} \sigma + \frac{40}{9} \sigma^2 + 8R\sigma, \\
c_3 &= -4\sigma r_1 + \frac{8i}{9} - \frac{20i}{9} \sigma + \frac{8i}{9} \sigma^2 + 4iR\sigma,
\end{align*}
\]

\( r_1 \), \( r_2 \), and \( r_3 \) are the first, second, and third resonance parameters, respectively.
Substituting the known coefficients into the recursive relation for $n = 4$, we have

\[
\begin{align*}
-a_4 - \sigma b_4 &= 0, \\
\frac{i}{\sigma} a_4 + ib_4 + c_4 &= -16\frac{9}{9} + 4i r_1 - \frac{16i}{3} \sigma r_1 - 20i\frac{2}{3} \sigma^2 r_1 \\
&\quad + 8\frac{8}{9} + 8\frac{8}{9} \sigma^2 - \frac{16}{9} \sigma^3 - 8R\sigma - 8R\sigma^2,
\end{align*}
\]

(3.5)

The system is consistent for arbitrary choice of $r_1$ if and only if

\[
\begin{align*}
1 - 11\sigma + (24 - 45R)\sigma^2 &+ (-14 + 9R)\sigma^3 + 4\sigma^4 = 0, \\
1 - 3\sigma + 2\sigma^2 &= 0.
\end{align*}
\]

Solving these, we have

\[
\sigma = 1/2, \quad R = 0; \quad \text{or} \quad \sigma = 1, \quad R = 1/9.
\]

Case 1A: $\sigma = 1/2, \quad B = 1, \quad R = 0$.

In this case, we solve (3.5) and get

\[
\begin{align*}
\theta' &= \frac{i}{2} + \frac{1}{2} \theta + \frac{1}{2} r_1 \theta^2 - ir_1 \theta^3 - \frac{1}{2} r_2 \theta^4 + \cdots, \\
Y &= -i\theta^{-2} + r_1 + 2ir_1 \theta + r_2 \theta^2 + \cdots, \\
Z &= \theta^{-2} + ir_1 - 2r_1 \theta - 3ir_1 \theta^2 + \cdots,
\end{align*}
\]

where $r_2$ is the second resonance parameter.

Now we introduce new variables $\xi$ and $\eta$ from the Laurent $\theta$-series of $Y$ and $Z$.

By cutting the $\theta$-series of $Y$ at $r_1$, we introduce $\xi$

\[
Y = -i\theta^{-2} + \xi.
\]

(3.6)

From the $\theta$-series of $\xi$, we have

\[
r_1 = \xi - 2i\xi \theta - (r_2 + 4\xi) \theta^2 + \cdots.
\]

Substituting this into the $\theta$-series of $Z$, we have

\[
Z = \theta^{-2} + i \xi - (ir_2 + 3i\xi) \theta^2 + \cdots.
\]
By cutting the $\theta$-series of $Z$ at $r_2$, we introduce $\eta$

$$Z = \theta^{-2} + i\xi + \eta\theta^2.$$  

(3.7)

Combining (3.6) and (3.7) with $X = \theta^{-1}$, we have a change of variable $(X, Y, Z) \leftrightarrow (\theta, \xi, \eta)$. Then it is easy to convert the Lorenz system (3.1) into the following

$$\begin{align*}
\theta' &= \frac{i}{2} + \frac{1}{3} \theta - \frac{1}{2} \xi^2, \\
\xi' &= -\xi - \eta\theta, \\
\eta' &= -2\eta + \xi\eta\theta.
\end{align*}$$

(3.8)

This is a mirror system of the Lorenz system in the case 1A of the branch $\theta' \sim i/2$.

The most important feature for the singularity analysis is that the system is regular near $\theta = 0$, which corresponds to the movable singularity of the Lorenz system.

**Case 1B**: $\sigma = 1, B = 2, R = 1/9$.

In this case, we get the following Laurent $\theta$-series

$$\begin{align*}
\theta' &= \frac{i}{2} + \frac{2}{3} \theta - r_1\theta^2 - \frac{16i}{3} r_1 \theta^3 - r_2\theta^4 + \cdots, \\
Y' &= -\frac{i}{2} \theta^{-2} + \frac{1}{3} \theta^{-1} + r_1 + \frac{16i}{3} r_1 \theta + r_2\theta^2 + \cdots, \\
Z' &= \frac{1}{2} \theta^{-2} + i r_1 - 4r_2\theta - \frac{32i}{3} r_1 \theta^2 + \cdots,
\end{align*}$$

where $r_1$ and $r_2$ can be arbitrary. By first cutting $Y$ at $r_1$ and then $Z$ at $r_2$, we introduce new variables $\xi$ and $\eta$ by

$$\begin{align*}
X &= \theta^{-1}, \\
Y &= \frac{i}{2} \theta^{-2} + \frac{1}{3} \theta^{-1} + \xi, \\
Z &= \frac{1}{2} \theta^{-2} + i \xi + \frac{4}{3} \xi \theta + \eta\theta^2.
\end{align*}$$

The transformation converts the Lorenz system (3.1) into the following mirror system

$$\begin{align*}
\theta' &= \frac{i}{2} + \frac{2}{3} \theta - \xi^2, \\
\xi' &= -\frac{8}{3} \xi - \eta\theta, \\
\eta' &= \frac{4}{3} \xi^3 - 2\eta + 2\xi\eta\theta.
\end{align*}$$
Case 2: $B = 1 - 3\sigma$.

The compatibility condition at the resonance $j = 4$ leads to the following condition

$$\sigma = 1/3, \quad B = 0, \quad R \text{ arbitrary.}$$

Under the condition, we get the following $\theta$-series

$$\begin{cases}
\theta' = i \frac{2}{3} - \frac{1}{3} r_1 \theta^2 - \frac{1}{3} r_2 \theta^4 + \cdots, \\
Y = -\frac{3i}{2} \theta^{-2} + \theta^{-1} + r_1 + r_2 \theta^2 + \cdots, \\
Z = \frac{3}{2} \theta^{-2} + 2i \theta^{-1} + ir_1 - 1 + R - \frac{4}{3} r_1 \theta + \cdots.
\end{cases}$$

Based on these we introduce new variables $\xi$ and $\eta$

$$\begin{cases}
X = \theta^{-1}, \\
Y = -\frac{3i}{2} \theta^{-2} + \theta^{-1} + \xi, \\
Z = \frac{3}{2} \theta^{-2} + 2i \theta^{-1} + i \xi - 1 + R - \frac{4}{3} \xi \theta + \eta \theta^2,
\end{cases}$$

by cutting the $\theta$-series of $Y$ at $r_1$ and then the $\theta$-series of $Z$ at $r_2$. Under the transformation, the Lorenz system becomes

$$\begin{cases}
\theta' = i \frac{2}{3} - \frac{1}{3} \xi \theta^2, \\
\xi' = -\eta \theta, \\
\eta' = -\frac{4}{9} \xi^2 - \frac{4}{3} \eta + \frac{2}{3} \xi \eta \theta.
\end{cases}$$

3.2. The Rikitake model. The Rikitake model

$$\begin{cases}
X' = -\gamma X + \beta Y + YZ, \\
Y' = -\gamma Y - \beta X + XZ, \\
Z' = -XY + \alpha,
\end{cases} \quad (3.9)$$

describes earth’s magneto-hydrodynamic dynamo. The dominant balance argument suggests us to introduce the indicial normalization $X = \theta^{-1}$ and try to find the Laurent $\theta$-series (2.1), with $l = m = 1$ and $a_*, b_*, c_*$ constants.

We substitute the $\theta$-series into the system. By comparing the coefficients of powers of $\theta$ on both sides, we get the equations for the leading coefficients

$$a_0 = -b_0 c_0, \quad -a_0 b_0 = c_0, \quad -a_0 c_0 = -b_0.$$
which gives four possible branches of leading behaviors

\[
(a_0, b_0, c_0) = \begin{cases}
(-i, 1, i) \\
(-i, -1, -i) \\
(i, 1, -i) \\
(i, -1, i)
\end{cases}
\]  

(3.10)

We also have the recursive relation

\[
\begin{cases}
a_n + c_0 b_n + b_0 c_n &= \delta_{1,n} \gamma - \beta b_{n-1} - \sum_{j=1}^{n-1} b_j c_{n-j}, \\
-b_0 a_n + (n-1) a_0 b_n - c_n &= -\delta_{1,n} \beta - \gamma b_{n-1} - \sum_{j=1}^{n-1} (j-1) a_{n-j} b_j, \\
-c_0 a_n + b_n + (n-1) a_0 c_n &= \delta_{2,n} \alpha - \sum_{j=1}^{n-1} (j-1) a_{n-j} c_j.
\end{cases}
\]  

(3.11)

Substituting (3.10) into the coefficient matrix on the left of (3.11), we see that the determinant of the coefficient matrix is \(-(n-2)^2\). Therefore there is one double resonance \(j = 2\). By checking out the compatibility conditions, we find exactly two cases.

From now on, we proceed with the first branch \((a_0, b_0, c_0) = (-i, 1, i)\). The discussion for the other branches is similar.

Case 1: \(\alpha = 0, \beta = 0\).

We get the following \(\theta\)-series

\[
\begin{align*}
\theta' &= -i - (ir_1 + r_2)\theta^2 + \cdots, \\
Y &= \theta^{-1} + r_1 \theta + \cdots, \\
Z &= i\theta^{-1} + \gamma + r_2 \theta + \cdots.
\end{align*}
\]

By cutting the \(\theta\)-series of \(Y\) at \(r_1\) and the \(\theta\)-series of \(Z\) at \(r_2\) (at the same time), we introduce new variables \(\xi\) and \(\eta\)

\[
\begin{cases}
X = \theta^{-1}, \\
Y = \theta^{-1} + \xi \theta, \\
Z = i\theta^{-1} + \gamma + \eta \theta.
\end{cases}
\]
The transformation converts the Rikitake system (3.9) into the following mirror system

\[
\begin{align*}
\theta' &= -i - (i\xi + \eta)\theta^2 - \gamma\xi\theta^3 - \xi\eta\theta^4, \\
\xi' &= -2\gamma\xi + i\xi^2\theta + \gamma\xi^2\theta^2 + \xi^2\eta\theta^3, \\
\eta' &= -i\gamma\xi + \eta^2\theta + \gamma\xi\eta\theta^2 + \xi\eta^2\theta^3.
\end{align*}
\]

(3.12)

**Case 2:** \(\alpha = 0, \gamma = 0\).

We get the following \(\theta\)-series

\[
\begin{align*}
\theta' &= -i + 2\beta\theta - (i\xi_1 + \eta)r_2\theta^2 + \cdots, \\
Y &= \theta^{-1} + 2i\beta + r_2\theta + \cdots, \\
Z &= i\theta^{-1} - \beta + r_2\theta + \cdots.
\end{align*}
\]

By cutting the \(\theta\)-series of \(Y\) at \(r_1\) and the \(\theta\)-series of \(Z\) at \(r_2\), we introduce new variables \(\xi\) and \(\eta\)

\[
\begin{align*}
X &= \theta^{-1}, \\
Y &= \theta^{-1} + 2i\beta + \xi\theta, \\
Z &= i\theta^{-1} - \beta + \eta\theta.
\end{align*}
\]

The corresponding mirror system is

\[
\begin{align*}
\theta' &= -i + 2\beta\theta - (i\xi + \eta)\theta^2 - 2i\beta\eta\theta^3 - \xi\eta\theta^4, \\
\xi' &= -2\beta\xi + 2i\beta\eta + i\xi^2\theta + 2i\beta\xi\eta\theta^2 + \xi^2\eta\theta^3, \\
\eta' &= \eta^2\theta + 2i\beta\eta^2\theta^2 + \xi\eta^2\theta^3.
\end{align*}
\]

### 3.3. The nonlinear Schrödinger equation.

It is well known that the nonlinear Schrödinger equation (NLS)

\[
iu_t + u_{xx} - 2|u|^2u = 0
\]

is completely integrable. To find its mirror system, we complexify all variables and write the NLS equation as a system

\[
\begin{align*}
iu_t + u_{xx} - 2|u|^2u &= 0, \\
-iv_t + v_{xx} - 2uv^2 &= 0,
\end{align*}
\]

(3.13)

in which \(u\) and \(v\) are treated as independent complex functions of \(x\) and \(t\).
The dominant balance argument suggests us to introduce the indicial normalization $u = \theta^{-1}$ and try to find the Laurent $\theta$-series:

\[
\begin{cases}
\theta_x = a_0 + a_1 \theta + a_2 \theta^2 + \cdots, \\
v = \theta^{-1}(b_0 + b_1 \theta + b_2 \theta^2 + \cdots),
\end{cases}
\]  

(3.14)

in which $a_*, b_*, c_*$ are functions of $t, \theta_t, \theta_{t^2}, \cdots$.

We substitute (3.14) into (3.13) to get the equation for the leading coefficients

\[2a_0^2 - 2b_0 = 0, \]  

(3.15)

and the recursive equation

\[
\begin{cases}
(n - 4)a_0a_n + 2b_n = F_n, \\
(n - 4)a_0b_0a_n + [4b_0 - (n^2 - 3n + 2)a_0^2]b_n = G_n,
\end{cases}
\]  

(3.16)

where

\[
\begin{align*}
F_n &= -\delta_{1,n} \theta_t - \sum_{j+k=n \atop j,k \neq n} (j-2)a_j a_k - \sum_{j+k=n-1} (\partial_x a_j)_k, \\
G_n &= -i(n-2)\theta_t b_{n-1} - 2 \sum_{j+k=n \atop j \neq n} b_j b_k + 2 \sum_{j+k=n-1} a_j a_k b_l \\
&\quad - \sum_{j+k+l=n-1 \atop j+k \neq n} (j+1)a_{j+1}a_k b_l - 2 \sum_{j+k+l=n-1 \atop j+k \neq n} (l+1)a_j a_k b_{l+1} \\
&\quad + \sum_{j+k+l=n-2 \atop j+k \neq n-1} (l+1)(l+2)a_j a_k b_{l+2} + \sum_{j+k+l=n-2} (k+1)(l+1)a_j a_k b_{l+1} \\
&\quad - i\theta_t b_{n-2} - \sum_{j+k+l=n-1 \atop j+k \neq n-1} (\partial_x a_j) b_l - 2 \sum_{j+k+l=n-1} a_j (\partial_x b_k)_l \\
&\quad + \sum_{j+k+l=n-1 \atop j+k \neq n-1} l(\partial_x a_j) b_l + 2 \sum_{j+k+l=n-1} (k+l)a_j (\partial_x b_k)_l + \sum_{j+k+l=n-2} (\partial_x a_j)_k
\end{align*}
\]

and $(\partial_x a_j)_k, (\partial_x b_k)_l, (\partial_x a_j)_k$ mean the following: Since $a_j$ is a function of $t, \theta_t, \theta_{t^2}, \cdots$, the partial derivative $\partial_x a_j$ is a function of $t, \theta_t, \theta_{t^2}, \cdots$, and the following $\theta$-series

\[
(\theta_x)_t = \sum_{j=0}^{\infty} [\partial_t a_j + (j + 1)a_j \theta_t] \theta^j, \quad (\theta_x)_{t^2}, \cdots
\]

Then we find the $\theta$-series for $\partial_x a_j$, in which $(\partial_x a_j)_k$ denotes the coefficient of $\theta^k$.

From (3.15), we find $a_0 = r_1(t), b_0 = r_1(t)^2$ for an arbitrary nonzero function $r_1$ (the first resonance parameter). From (3.16) we further find the $\theta$-series for $u_x, v,$
functions of $t$.

If we change $\theta \to \text{v}_x(\text{r}_2, \text{r}_3)$ is the same as

$$
\begin{align*}
\frac{\partial \theta}{\partial x} & = -\xi, \\
\frac{\partial \xi}{\partial x} & = 2\theta^2\eta - i\theta_t, \\
\frac{\partial \eta}{\partial x} & = \zeta, \\
\frac{\partial \zeta}{\partial x} & = -2\theta\eta^2 - i\eta_t.
\end{align*}
$$

(3.17)

Note that the mirror system (3.17) is the same as

$$
\begin{align*}
\frac{\partial \theta}{\partial x} & = -2\theta^2\eta + i\theta_t, \\
\frac{\partial \eta}{\partial x} & = -2\theta\eta^2 - i\eta_t.
\end{align*}
$$

If we change $x$ to $ix$, this becomes the system (3.13) we started with! The transform $(\theta, \eta) \to (u, v)$ is

$$
\begin{align*}
u & = \theta^{-1}, \\
v & = \theta^2\theta^{-1} - i\theta_t + \eta^2.
\end{align*}
$$
The inverse transform \((u, v) \rightarrow (\theta, \eta)\) is

\[
\begin{align*}
\theta &= u^{-1}, \\
\eta &= u_x^2 u^{-1} - iu_t + u^2 v.
\end{align*}
\]

4. **Convergence of the Laurent series in the Painlevé test.** In [3], we made use of the mirror systems of single high order completely integrable equations to give conceptual proofs of the convergence of the Laurent series obtained from applying the Painlevé test. The method involves the following steps:

1. Convert the Laurent series obtained from the Painlevé test into an initial value problem for the appropriate mirror system;
2. Apply the Cauchy-Kowalevski theorem to the initial value problem and conclude the convergence of the power series solutions of the mirror system;
3. The convergent power series solutions of the mirror system lead to convergent Laurent series solutions of the original system, because of the equivalence between the original system and the mirror system;
4. Compare the Laurent series from step 3 with the series obtained from the Painlevé test explicitly. If the two series are the same up to the order where all the resonances appear, then the two series must be the same (because the whole series are determined by those leading terms).

A consequence of these steps is the convergence of the Laurent series obtained form the Painlevé test. Such convergence can be considered as the justification of the Painlevé test.

The idea works equally well with systems. We present the details only for one case of the Lorenz system. We will also present the outline for the other cases.
4.1. One case of the Lorenz system. For the case $1A: \sigma = 1/2, B = 1, R = 0$, the Painlevé test produces the following formal Laurent series solution

$$
\begin{align*}
X &= -2i t^{-1} + \frac{i}{2} + \left(-\frac{i}{4} + \frac{1}{2}\tilde{r}_1\right) t + \left(\frac{5i}{32} - \frac{3}{8}\tilde{r}_1\right) t^2 \\
&\quad + \left(-\frac{5i}{192} + \frac{1}{16}\tilde{r}_1 + \frac{1}{6}\tilde{r}_2\right) t^3 + \cdots, \\
Y &= 4it^{-2} - 2it^{-1} + \tilde{r}_1 + \left(\frac{3i}{8} - \tilde{r}_1\right) t + \tilde{r}_2 t^2 + \cdots, \\
Z &= -4t^{-2} + 2t^{-1} + i\tilde{r}_1 + \left(-\frac{3}{8} - i\tilde{r}_1\right) t \\
&\quad + \left(\frac{29}{96} + \frac{5i}{8}\tilde{r}_1 + \frac{1}{4}\tilde{r}_1^2 - \frac{2i}{3}\tilde{r}_2\right) t^2 + \cdots,
\end{align*}
$$

(4.1)

where $\tilde{r}_1$ and $\tilde{r}_2$ are the resonance parameters in the Painlevé test, and we use $t$ instead of $(t - t_0)$ because of the autonomous system. To show that these series are convergent for small $t$ and arbitrary $\tilde{r}_1$ and $\tilde{r}_2$ (the size of $t$ may depend on $\tilde{r}_1$ and $\tilde{r}_2$), we convert (4.1) to an initial value problem for the mirror system.

We substitute the formal Laurent series (4.1) into the transformation $X = \theta^{-1}$, (3.6), and (3.7) to find the formal power series for $\theta$, $\xi$, and $\eta$. The computation leads to the following initial data

$$
\theta(0) = 0, \quad \xi(0) = -\frac{5i}{4} + 3\tilde{r}_1, \quad \eta(0) = -\frac{23}{12} - 5i\tilde{r}_1 + \tilde{r}_1^2 + \frac{28i}{3}\tilde{r}_2,
$$

for the mirror system (3.8).

By the Cauchy theorem, we know that the initial value problem for the mirror system (3.8) has a power series solution which is convergent in a neighborhood of 0. We may further find the power series for $\theta$, $\xi$, and $\eta$ by the usual method such as
undetermined coefficients

\[
\begin{align*}
\theta &= \frac{i}{2}t^2 + \frac{i}{8}t^2 + \left( -\frac{i}{32} + \frac{1}{8}r_1 \right) t^3 + \left( \frac{i}{64} - \frac{1}{32}r_1 \right) t^4 \\
&\quad + \left( \frac{17i}{1536} - \frac{5}{128}r_1 - \frac{i}{32}r_2 + \frac{1}{24}r_2 \right) t^5 + \cdots, \\
\xi &= -\frac{5i}{4} + 3r_1 + \left( \frac{5i}{4} - 3r_1 \right) t + \left( \frac{31i}{96} + \frac{7}{8}r_1 + \frac{i}{4}r^2 + \frac{5}{3}r_2 \right) t^2 + \cdots, \\
\eta &= -\frac{23}{12} - 5ir_1 + r_1^2 + \frac{28i}{3}r_2 + \cdots.
\end{align*}
\]

Substituting these series back into \( X = \theta^{-1}, (3.6), \) and (3.7), we find the convergent (i.e., not just formal) power series for \( X, \) \( Y, \) and \( Z. \) The computation shows that the result is exactly (4.1). Thus we conclude that the Laurent series (4.1) are convergent.

4.2. Other cases and systems. For the case 1B (\( \sigma = 1, B = 2, R = 1/9 \)) of the Lorenz system, the Painlevé test produces the following formal Laurent series solution

\[
\begin{align*}
X &= -2it^{-1} + \frac{2i}{3} + \left( -\frac{2i}{3} + \bar{r}_1 \right) t + \left( \frac{32i}{27} - 2\bar{r}_1 \right) t^2 \\
&\quad + \left( \frac{32i}{81} + \frac{2}{3}r_1 + \frac{1}{3}r_2 \right) t^3 + \cdots, \\
Y &= 2it^{-2} - 2it^{-1} + \bar{r}_1 + \left( \frac{46i}{27} - 3\bar{r}_1 \right) t + \bar{r}_2 t^2 + \cdots, \\
Z &= -2t^{-2} + \frac{4}{3}t^{-1} + \frac{2}{9} + i\bar{r}_1 + \left( -\frac{20}{27} - \frac{4i}{3}\bar{r}_1 \right) t \\
&\quad + \left( \frac{142}{81} + \frac{8i}{3}\bar{r}_1 + \frac{1}{2}r_1^2 - \frac{2i}{3}r_2 \right) t^2 + \cdots.
\end{align*}
\]

The convergence of the series may be proved by considering the following initial value

\[
\theta(0) = 0, \quad \xi(0) = -\frac{16i}{9} + 3r_1, \quad \eta(0) = -\frac{1336}{81} - \frac{80i}{3}r_1 - 2\bar{r}_1^2 + \frac{20i}{3}\bar{r}_2,
\]

for the corresponding mirror system.

For the case 2 (\( \sigma = 1/3, B = 0, R \) arbitrary), we should consider the following initial data

\[
\theta(0) = 0, \quad \xi(0) = 3\bar{r}_1, \quad \eta(0) = -\frac{2}{3}r_1^2 + \frac{20i}{3}\bar{r}_2.
\]
for the corresponding mirror system. This leads to the convergence of the following Laurent series obtained from the Painlevé test

\[
\begin{aligned}
X &= -2it^{-1} + \frac{1}{3} \bar{r}_1 t + \frac{2}{9} \bar{r}_2 t^2 + \cdots, \\
Y &= 6it^{-2} - 2it^{-1} + \bar{r}_1 + \frac{1}{3} \bar{r}_1 t + \bar{r}_2 t^2 + \cdots, \\
Z &= -6t^{-2} + 4t^{-1} - 1 + R + i\bar{r}_1 - \frac{4i}{3} \bar{r}_1 t + \left( \frac{1}{6} \bar{r}_1^2 - \frac{2i}{3} \bar{r}_2 \right) t^2 + \cdots.
\end{aligned}
\]

For the branch of the Rikitake model considered in Section 3.2 in case \(\alpha = \beta = 0\), we solve the mirror system (3.12) with the initial data

\[
\begin{align*}
\theta(0) &= 0, & \xi(0) &= 2i\bar{r}_1 + \bar{r}_2, & \eta(0) &= -\bar{r}_1 + 2i\bar{r}_2.
\end{align*}
\]

This leads to the convergence of the following Laurent series

\[
\begin{aligned}
X &= it^{-1} + (-\bar{r}_1 + i\bar{r}_2) t + \cdots, \\
Y &= it^{-1} + \bar{r}_1 t + \cdots, \\
Z &= -t^{-1} + \gamma + \bar{r}_2 t + \cdots,
\end{aligned}
\]

obtained in the Painlevé test for the Rikitake model. The convergence of the Laurent series in other cases of the Rikitake model can be proved similarly.

By solving the mirror system (3.17) for the NLS system (3.13) with the following initial data along the initial manifold \(x = \psi(t)\):

\[
\begin{aligned}
\theta &= 0, \\
\xi &= \bar{r}_1^{-1}, \\
\eta &= \frac{1}{2} \psi' \bar{r}_1' + \frac{1}{4} \psi'' \bar{r}_1 + 6\bar{r}_2, \\
\zeta &= \frac{1}{72} \psi' \bar{r}_1 + \frac{i}{12} \psi' \psi'' \bar{r}_1 + \frac{1}{9} \bar{r}_1^{-1} \bar{r}_2^2 - \frac{i}{18} \psi'^2 \bar{r}_1' + \frac{1}{12} \bar{r}_1'' - 2i\psi' \bar{r}_2 + 10\bar{r}_3,
\end{aligned}
\]

where \(\psi, \bar{r}_1, \bar{r}_2, \text{ and } \bar{r}_3\) are arbitrary analytic functions and \(\bar{r}_1 \neq 0\), we can prove the
convergence of the Laurent series

\[
\begin{align*}
  u &= \bar{r}_1(x - \psi)^{-1} + \frac{i}{2} \psi' \bar{r}_1 + \left( -\frac{1}{12} \psi'^2 \bar{r}_1 + \frac{i}{6} \bar{r}_1^1 \right) (x - \psi) \\
    &\quad + \bar{r}_2(x - \psi)^2 + \bar{r}_3(x - \psi)^3 + \cdots, \\
  v &= \bar{r}_1^{-1}(x - \psi)^{-1} - \frac{i}{2} \psi' \bar{r}_1^{-1} + \left( -\frac{1}{12} \psi'^2 \bar{r}_1^{-1} + \frac{i}{6} \bar{r}_1^{-2} \bar{r}_1^1 \right) (x - \psi) \\
    &\quad + \left( \frac{1}{4} \psi'' \bar{r}_1^{-1} - \bar{r}_1^{-2} \bar{r}_2 \right) (x - \psi)^2 \\
    &\quad + \left( \frac{i}{6} \psi' \psi'' \bar{r}_1^{-1} + \frac{1}{12} \bar{r}_1^{-3} \bar{r}_1^2 - \frac{1}{12} \bar{r}_1^{-2} \bar{r}_1^2 + \bar{r}_1^{-2} \bar{r}_3 \right) (x - \psi)^3 + \cdots.
\end{align*}
\]

These are the Laurent series obtained in the Painlevé test.
